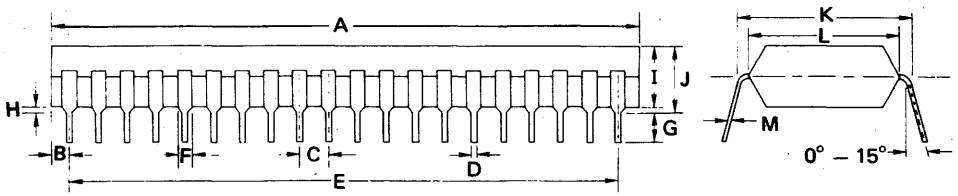
The Internal Timer is a 14-bit binary down counter capable of operating in 4 modes. Its desired mode of operation is programmable at any time during operation. Any TTL clock meeting timer in requirements (See AC Characteristics) may be used as a time base and fed to the timer input. The timer output may be looped around and cause an interrupt or used as I/O control. The operational modes are defined as follows and programmed along with the 6 high bits of timer data.



M2	M1	Operation
0	0	High at Start, Low During Second Half of Count
0	1	Square Wave (Period = Count Length, Auto Reload at TC)
1	0	Single Pulse at TC
1	1	Single Pulse at TC with Auto Reload

Programming the timer requires two words to be written to the μPD8155/8156 at I/O address XXXXX100 and XXXXX101 for the low and high order bytes respectively. Valid count length must be between 2_H and $3FFF_H$. The bit assignments for the high and low programming words are as follows:

Word	Bit Pattern								I/O Address
High Byte	M_2	M_1	T13	T12	T11	T10	T9	T8	XXXXX101
Low Byte	T7	T6	T5	T4	T3	T2	T1	T0	XXXXX100

The control of the timer is performed by TM2 and TM1 of the Command Status Word.

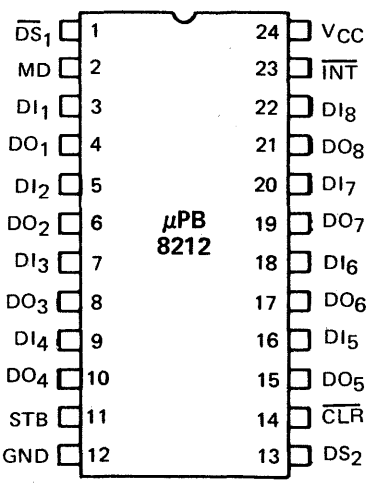
EIGHT-BIT INPUT/OUTPUT PORT

DESCRIPTION



The μPB8212 input/output port consists of an 8-bit latch with three-state output buffers along with control and device selection logic. Also included is a service request flip-flop for the control and generation of interrupts to the microprocessor.

The device is multimode in nature and can be used to implement latches, gated buffers or multiplexers. Thus, all of the principal peripheral and input/output functions of a microcomputer system can be implemented with this device.

FEATURES

- Fully Parallel 8-Bit Data Register and Buffer
- Service Request Flip-Flop for Interrupt Generation
- Low Input Load Current – 0.25 mA Max.
- Three State Outputs
- Outputs Sink 15 mA
- 3.65V Output High Voltage for Direct Interface to 8080A Processor
- Asynchronous Register Clear
- Replaces Buffers, Latches and Multiplexers in Microcomputer Systems
- Reduces System Package Count
- Available in 24-pin Plastic and Cerdip Packages

FUNCTIONAL DESCRIPTION

Data Latch

The 8 flip-flops that compose the data latch are of a "D" type design. The output (Q) of the flip-flop follows the data input (D) while the clock input (C) is high. Latching occurs when the clock (C) returns low.

The data latch is cleared by an asynchronous reset input ($\overline{CLR}$).
(Note: Clock (C) Overrides Reset ($\overline{CLR}$).)

Output Buffer

The output of the data latch (Q) are connected to three-state, non-inverting output buffers. These buffers have a common control line (EN); enabling the buffer to transmit the data from the outputs of the data latch (Q) or disabling the buffer, forcing the output into a high impedance state (three-state).

This high-impedance state allows the designer to connect the μPB8212 directly to the microprocessor bi-directional data bus.

Control Logic

The μPB8212 has four control inputs: $\overline{DS}_1$, DS_2, MD and STB. These inputs are employed to control device selection, data latching, output buffer state and the service request flip-flop.

$\overline{DS}_1$, DS_2 (Device Select)

These two inputs are employed for device selection. When $\overline{DS}_1$ is low and DS_2 is high ($\overline{DS}_1 \cdot DS_2$) the device is selected. In the selected state the output buffer is enabled and the service request flip-flop (SR) is asynchronously set.

Service Request Flip-Flop (SR)

The (SR) flip-flop is employed to generate and control interrupts in microcomputer systems. It is asynchronously set by the $\overline{CLR}$ input (active low). When the (SR) flip-flop is set it is in the non-interrupting state.

The output (Q) of the (SR) flip-flop is connected to an inverting input of a "NOR" gate. The other input of the "NOR" gate is non-inverting and is connected to the device selection logic ($\overline{DS}_1 \cdot DS_2$). The output of the "NOR" gate ($\overline{INT}$) is active low (interrupting state) for connection to active low input priority generating circuits.

MD (Mode)

This input is employed to control the state of the output buffer and to determine the source of the clock input (C) to the data latch.

When MD is in the output mode (high) the output buffers are enabled and the source of clock (C) to the data latch is from the device selection logic ($\overline{DS}_1 \cdot DS_2$).

When MD is in the input mode (low) the output buffer state is determined by the device selection logic ($\overline{DS}_1 \cdot DS_2$) and the source of clock (C) to the data latch is the STB (Strobe) input.

STB (Strobe)

STB is employed as the clock (C) to the data latch for the input mode (MD = 0) and to synchronously reset the service request flip-flop (SR).

Note that the SR flip-flop triggers on the negative edge of STB which overrides $\overline{CLR}$.

ABSOLUTE MAXIMUM RATINGS*

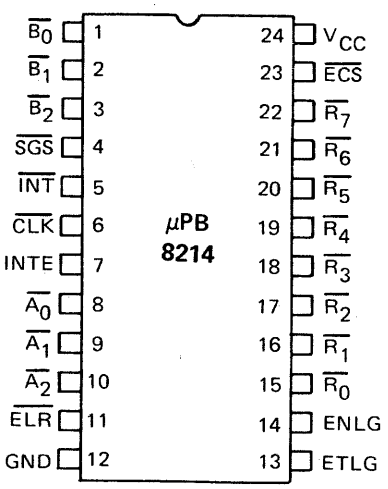
PRIORITY INTERRUPT CONTROLLER

DESCRIPTION

The μPB8214 is an eight-level priority interrupt controller. Designed to simplify interrupt driven microcomputer systems, the μPB8214 requires a single +5V power supply and is packaged in a 24 pin plastic Dual-in-line package.



The μPB8214 accepts up to eight interrupts, determines which has the highest priority and then compares that priority with a software created current status register. If the incoming requires is of a higher priority than the interrupt currently being serviced, an interrupt request to the processor is generated. Vector information that identifies the interrupting device is also generated.

The interrupt structure of the microcomputer system can be expanded beyond eight interrupt levels by cascading μPB8214s. The μPB8214's interrupt and vector information outputs are open collector and control signals are provided to simplify expansion of the interrupt structure.

FEATURES

- Eight Priority Levels
- Current Status Register and Priority Comparator
- Easily Expanded Interrupt Structure
- Single +5 Volt Supply

BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

General

The μPB8214 is an LSI device designed to simplify the circuitry required to implement an interrupt driven microcomputer system. Up to eight interrupting devices can be connected to a μPB8214, which will assign priority to incoming interrupt requests and accept the highest. It will also compare the priority of the highest incoming request with the priority of the interrupt being serviced. If the serviced interrupt has a higher priority, the incoming request will not be accepted.

A system with more than eight interrupting devices can be implemented by interconnecting additional μPB8214s. In order to facilitate this expansion, control signals are provided for cascading the controllers so that there is a priority established among the controllers. In addition, the interrupt and vector information outputs are open collector.

Priority Encoder and Request Latch

The priority encoder portion of the μPB8214 accepts up to eight active low interrupt requests ($\overline{R_0}$–$\overline{R_7}$). The circuit assigns priority to the incoming requests, with $\overline{R_7}$ having the highest priority and $\overline{R_0}$ the lowest. If two or more requests occur simultaneously, the μPB8214 accepts the one having the highest priority. Once an incoming interrupt request is accepted, it is stored by the request latch and a three-bit code is output. As shown in the following table, the outputs, ($\overline{A_0}$–$\overline{A_2}$) are the complement of the request level (modulo 8) and directly correspond to the bit pattern required to generate the one byte RESTART (RST) instructions recognized by an 8080A. Simultaneously with the $\overline{A_0}$–$\overline{A_2}$ outputs, a system interrupt request ($\overline{INT}$) is output by the μPB8214. It should be noted that incoming interrupt requests that are *not* accepted are not latched and must remain as an input to the μPB8214 in order to be serviced.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)

RESTART GENERATION TABLE

PRIORITY REQUEST		RST	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
			1	1	$\overline{A_2}$	$\overline{A_1}$	$\overline{A_0}$	1	1	1
LOWEST	$\overline{R_0}$	7	1	1	1	1	1	1	1	1
	$\overline{R_1}$	6	1	1	1	1	0	1	1	1
	$\overline{R_2}$	5	1	1	1	0	1	1	1	1
	$\overline{R_3}$	4	1	1	1	0	0	1	1	1
	$\overline{R_4}$	3	1	1	0	1	1	1	1	1
	$\overline{R_5}$	2	1	1	0	1	0	1	1	1
	$\overline{R_6}$	1	1	1	0	0	1	1	1	1
HIGHEST	$\overline{R_7}$	0*	1	1	0	0	0	1	1	1

*CAUTION: RST 0 will vector the program counter to location 0 (zero) and invoke the same routine as the "RESET" input to 8080A.

Current Status Register

The current status register is designed to prevent an incoming interrupt request from overriding the servicing of an interrupt with higher priority. Via software, the priority level of the interrupt being serviced by the microprocessor is written into the current status register on $\overline{B_0}$–$\overline{B_2}$. The bit pattern written should be the complement of the interrupt level.

The interrupt level currently being serviced is written into the current status register by driving $\overline{ECS}$ (Enable Current Status) low. The μPB8214 will only accept interrupts with a higher priority than the value contained by the current status register. Note that the programmer is free to use the current status register for other than as above. Other levels may be written into it. The comparison may be completely disabled by driving $\overline{SGS}$ (Status Group Select) low when $\overline{ECS}$ is driven low. This will cause the μPB8214 to accept incoming interrupts only on the basis of their priority to each other.

Priority Comparator

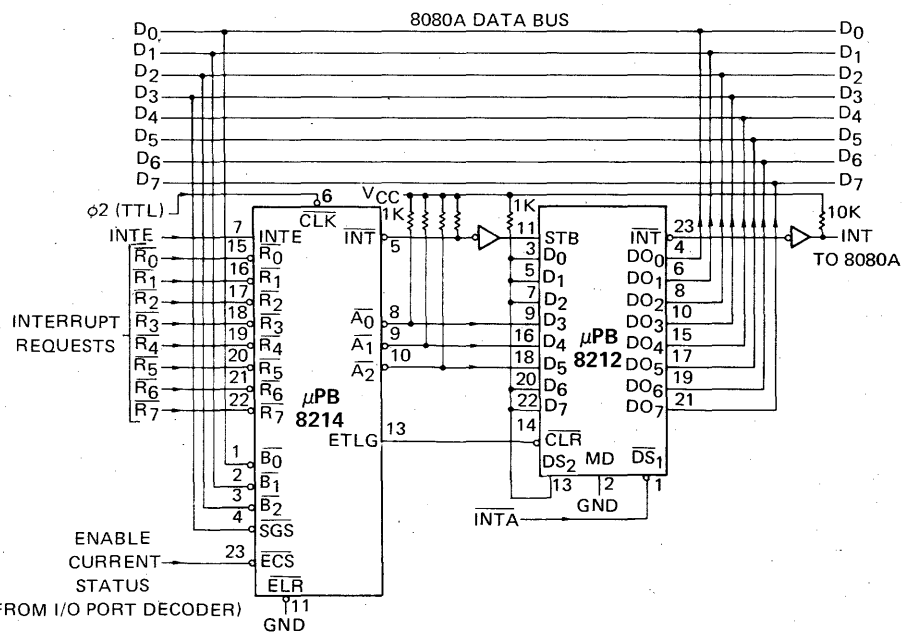
The priority comparator circuitry compares the level of the interrupt accepted by the priority encoder and request latch with the contents of the current status register. If the incoming request has a priority level higher than that of the current status register, the $\overline{INT}$ output is enabled. Note that this comparison can be disabled by loading the current status register with $\overline{SGS}$=0.

Expansion Control Signals

A microcomputer design may often require more than eight different interrupts. The μPB8214 is designed so that interrupt system expansion is easily performed via the use of three signals: ETLG (Enable This Level Group); ENLG (Enable Next Level Group); and $\overline{ELR}$ (Enable Level Read). A high input to ETLG indicates that the μPB8214 may accept an interrupt. In a typical system, the ENLG output from one μPB8214 is connected to the ETLG input of another μPB8214, etc. The ETLG of the μPB8214 with the highest priority is tied high. This configuration sets up priority among the cascaded μPB8214's. The ENLG output will be high for any device that does not have an interrupt pending, thereby allowing a device with lower priority to accept interrupts. The $\overline{ELR}$ input is basically a chip enable and allows hardware or software to selectively disable/enable individual μPB8214's. A low on the $\overline{ELR}$ input enables the device.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)



Interrupt Control Circuitry

The μPB8214 contains two flip-flops and several gates which determine whether an accepted interrupt request to the μPB8214 will generate a system interrupt to the 8080A. A condition gate drives the D input of the interrupt flip-flop whenever an interrupt request has been completely accepted. This requires that: the ETLG (Enable This Level Group) and INTE (Interrupt Enable) inputs to the μPB8214 are high; the $\overline{ELR}$ input is low; the incoming request must be of a higher priority than the contents of the current status register; and the μPB8214 must have been enabled to accept interrupt requests by the clearing of the interrupt disable flip-flop.

Once the condition gate drives the D input of the interrupt flip-flop high, a system interrupt ($\overline{INT}$) to the 8080A is generated on the next rising edge of the $\overline{CLK}$ input to the μPB8214. This $\overline{CLK}$ input is typically connected to the $\phi 2$ (TTL) output of an 8224 so that 8080A set-up time specifications are met. When $\overline{INT}$ is generated, it sets the interrupt disable flip-flop so that no additional system interrupts will be generated until it is reset. It is reset by driving $\overline{ECS}$ (Enable Current Status) low, thereby writing into the current status register.

It should be noted that the open collector $\overline{INT}$ output from the μPB8214 is active for only one clock period and thus must be externally latched for inputting to the 8080A. Also, because the $\overline{INT}$ output is open collector, when μPB8214's are cascaded, an $\overline{INT}$ output from any one will set all of the interrupt disable flip-flops in the array. Each μPB8214's interrupt disable flip-flop must then be cleared individually in order to generate subsequent system interrupts.

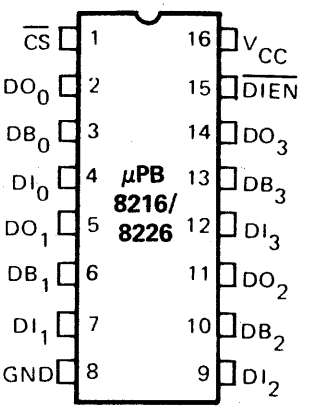
4 BIT PARALLEL BIDIRECTIONAL BUS DRIVER



DESCRIPTION

All inputs are low power TTL compatible. For driving MOS, the DO outputs provide a high 3.65V (V_{OH}), and for high capacitance terminated bus structures, the DB outputs provide a high 55 mA (I_{OL}) capability.

FEATURES

- Data Bus Buffer Driver for μCOM-8 Microprocessor Family
- Low Input Load Current – 0.25 mA Maximum
- High Output Drive Capability for Driving System Data Bus
- 3.65V Output High Voltage for Direct Interface to μCOM-8 Microprocessor Family
- Three State Outputs
- Reduces System Package Count
- Available in 16 pin packages: Cerdip and Plastic

PIN CONFIGURATION

PIN NAMES

$DB_0 - DB_3$	Data Bus Bi-Directional
$DI_0 - DI_3$	Data Input
$DO_0 - DO_3$	Data Output
$\overline{DIEN}$	Data in Enable Direction Control
$\overline{CS}$	Chip Select

μPB8216/8226

FUNCTIONAL DESCRIPTION

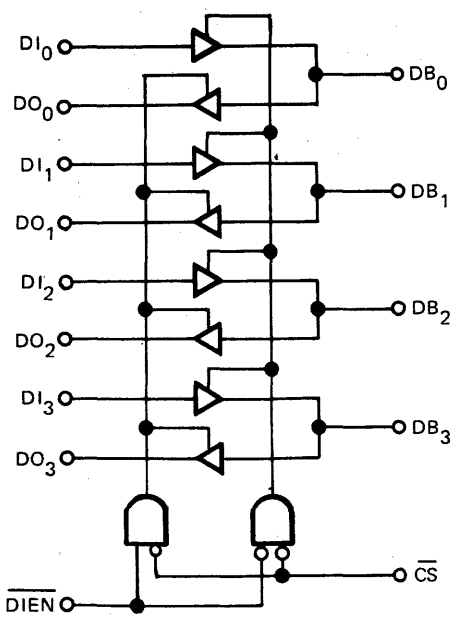
Microprocessors like the μPD8080A are MOS devices and are generally capable of driving a single TTL load. This also applies to MOS memory devices. This type of drive is sufficient for small systems with a few components, but often it is necessary to buffer the microprocessor and memories when adding components or expanding to a multi-board system.

The μPD8216/8226 is a four bit bi-directional bus driver specifically designed to buffer microcomputer system components.

Bi-Directional Driver

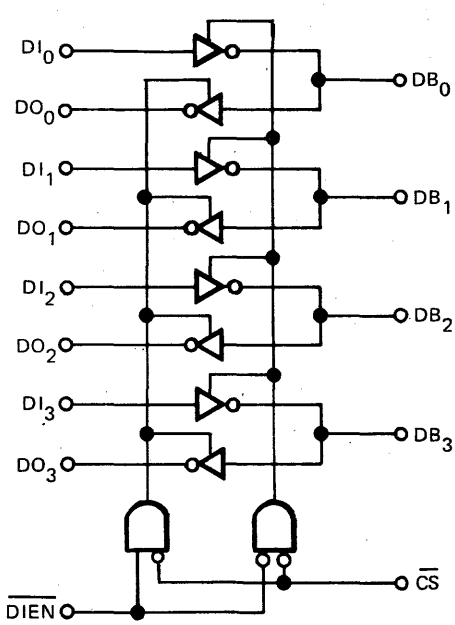
Each buffered line of the four bit driver consists of two separate buffers. They are three state in nature to achieve direct bus interface and bi-directional capability. On one side of the driver the output of one buffer and the input of another are tied together (DB), this is used to interface to the system side components such as memories, I/O, etc. Its interface is directly TTL compatible and it has high drive (55 mA). For maximum flexibility on the other side of the driver the inputs and outputs are separate. They can be tied together so that the driver can be used to buffer a true bi-directional bus such as the 8080A Data Bus. The DO outputs on this side of the driver have a special high voltage output drive capability (3.65V) so that direct interface to the 8080A processor is achieved with an adequate amount of noise immunity (650 mV worst case).

Control Gating $\overline{CS}$, $\overline{DIEN}$



The $\overline{CS}$ input is used for device selection. When $\overline{CS}$ is "high" the output drivers are all forced to their high-impedance state. When it is "low" the device is selected (enabled) and the data flow direction is determined by the $\overline{DIEN}$ input.

The $\overline{DIEN}$ input controls the data flow direction (see Block Diagrams for complete truth table). This directional control is accomplished by forcing one of the pair of buffers to its high impedance state. This allows the other to transmit its data. This is accomplished by a simple two gate circuit.



The μPB8216/8226 is a device that will reduce component count in microcomputer systems and at the same time enhance noise immunity to assure reliable, high performance operation.

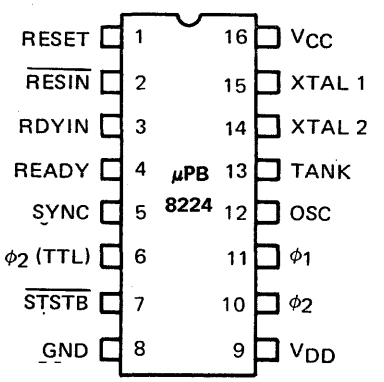
CLOCK GENERATOR AND DRIVER FOR 8080A PROCESSORS

DESCRIPTION

The μPB8224 is a single chip clock generator and driver for 8080A processors. The clock frequency is determined by a user specified crystal and is capable of meeting the timing requirements of the entire 8080A family of processors. MOS and TTL level clock outputs are generated.



Additional logic circuitry of the μPB8224 provides signals for power-up reset, an advance status strobe and properly synchronizes the ready signal to the processor. This greatly reduces the number of chips needed for 8080A systems.

The μPB8224 is fabricated using NEC's Schottky bipolar process.

FEATURES

- Crystal Controlled Clocks
- Oscillator Output for External Timing
- MOS Level Clocks for 8080A Processor
- TTL Level Clock for DMA Activities
- Power-up Reset for 8080A Processor
- Ready Synchronization
- Advanced Status Strobe
- Reduces System Package Count
- Available in 16-pin Cerdip and Plastic Packages

Clock Generator

The clock generator circuitry consists of a crystal controlled oscillator and a divide-by-nine counter. The crystal frequency is a function of the 8080A processor speed and is basically nine times the processor frequency, i.e.:

$$\text{Crystal frequency} = \frac{9}{t_{CY}}$$

where t_{CY} is the 8080A processor clock period.

A series resonant fundamental mode crystal is normally used and is connected across input pins XTAL1 and XTAL2. If an overtone mode crystal is used, an additional LC network, AC coupled to ground, must be connected to the TANK input of the μPB8224 as shown in the following figure.

The formula for the LC network is:

$$LC = \left(\frac{1}{2\pi F}\right)^2$$

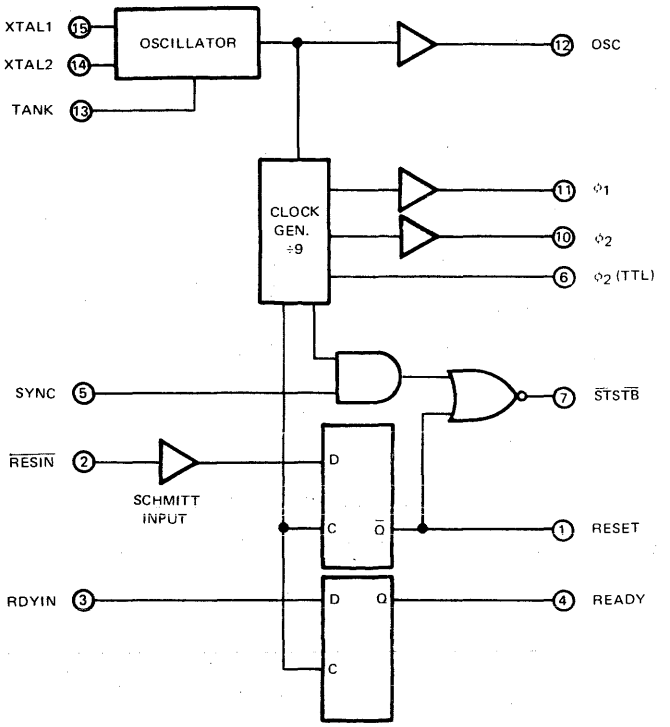
where F is the desired frequency of oscillation.

The output of the oscillator is input to the divide-by-nine counter. It is also buffered and brought out on the OSC pin, allowing this stable, crystal controlled source to be used for derivation of other system timing signals. The divide-by-nine counter generates the two non-overlapping processor clocks, ϕ_1 and ϕ_2, which are buffered and at MOS levels, a TTL level ϕ_2 and internal timing signals.

The ϕ_1 and ϕ_2 high level outputs are generated in a 2-5-2 digital pattern, with ϕ_1 being high for two oscillator periods, ϕ_2 being high for five oscillator periods, and then neither being high for two oscillator periods. The TTL level ϕ_2,ϕ_2 (TTL), is normally used for DMA activities by gating the external device onto the 8080A bus once a Hold Acknowledge (HLDA) has been issued.

Additional Logic

In addition to the clock generator circuitry, the μPB8224 contains additional logic to aid the system designer in the proper timing of several interface signals.



The $\overline{\text{STSTB}}$ signal indicates, at the earliest possible moment, when the status signals output from the 8080A processor are stable on the data bus. $\overline{\text{STSTB}}$ is designed to connect directly to the μPB8228 System Controller and automatically resets the μPB8228 during power-on Reset.

The $\overline{\text{RESIN}}$ input to the μPB8224 is used to automatically generate a RESET signal to the 8080A during power initialization. The slow rise of the power supply voltage in an external RC network is sensed by an internal Schmitt Trigger. The output of the Schmitt Trigger is gated to generate an 8080A compatible RESET. An active low manual switch may also be attached to the RC circuit for manual system reset.

The RDYIN input to the μPB8224 accepts an asynchronous "wait request" and generates a READY output to the 8080A that is fully synchronized to meet the 8080A timing requirements.

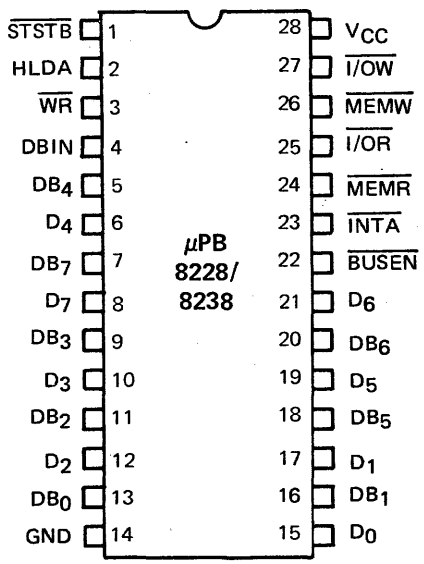
8080A SYSTEM CONTROLLER AND BUS DRIVER

DESCRIPTION

The μPB8228/8238 is a single chip controller and bus driver for 8080A based systems. All the required interface signals necessary to connect RAM, ROM and I/O components to a μPD8080A are generated.

The μPB8228/8238 provides a bi-directional three-state bus driver for high TTL fan-out and isolation of the processor data bus from the system data bus for increased noise immunity.



The system controller portion of the μPB8228/8238 consists of a status latch for definition of processor machine cycles and a gating array to decode this information for direct interface to system components. The controller can enable gating of a multi-byte interrupt onto the data bus or can automatically insert a RESTART 7 onto the data bus without any additional components.

Two devices are provided. The μPB8228 for small systems without tight write timing constraints and the μPB8238 for larger systems.

FEATURES

- System Controller for 8080A Systems
- Bi-Directional Data Bus for Processor Isolation
- 3.60V Output High Voltage for Direct Interface to 8080A Processor
- Three State Outputs on System Data Bus
- Enables Use of Multi-Byte Interrupt Instructions
- Generates RST 7 Interrupt Instruction
- μPB8228 for Small Memory Systems
- μPB8238 for Large Memory Systems
- Reduces System Package Count
- Schottky Bipolar Technology

FUNCTIONAL DESCRIPTION

Bi-Directional Bus Driver

The eight bit, bi-directional bus driver provides buffering between the processor data bus and the system data bus. On the processor side, the μPB8228/8238 exceeds the minimum input voltage requirements (3.0V) of the μPD8080A. On the system side, the driver is capable of adequate drive current (10 mA) for connection of a large number of memory and I/O devices to the bus. Signal flow in the bus driver is controlled by the gating array and its outputs can be forced into a high impedance state by use of the $\overline{\text{BUSEN}}$ input.

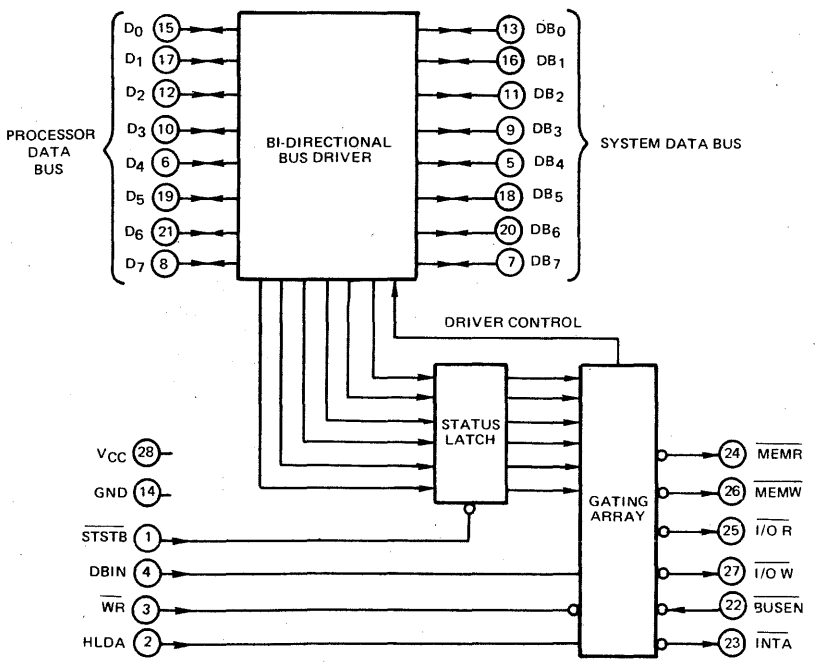
Status Latch

The Status Latch in the μPB8228/8238 stores the status information placed on the data bus by the 8080A at the beginning of each machine cycle. The information is latched when $\overline{\text{STSTB}}$ goes low and is then decoded by the gating array for the generation of control signals.

Gating Array

The Gating Array generates "active low" control signals for direct interfacing to system components by gating the contents of the status latch with control signals from the 8080A.

$\overline{\text{MEM/R}}$, $\overline{\text{I/OR}}$ and $\overline{\text{INTA}}$ are generated by gating the DBIN signal from the processor with the contents of the status latch. $\overline{\text{I/OR}}$ is used to enable an I/O input onto the system data bus. $\overline{\text{MEM/R}}$ is used to enable a memory input.



$\overline{\text{INTA}}$ is normally used to gate an interrupt instruction onto the system data bus. When used with the μPD8080A processor, the μPB8228/8238 will decode an interrupt acknowledge status word during all three machine cycles for a multi-byte interrupt instruction. For 8080A type processors that do not generate an interrupt acknowledge status word during the second and third machine cycles of a multi-byte interrupt instruction, the μPB8228/8238 will internally generate an $\overline{\text{INTA}}$ pulse for those machine cycles.

The μPB8228/8238 also provides the designer the ability to place a single interrupt instruction onto the bus without adding additional components. By connecting the +12 volt supply to the $\overline{\text{INTA}}$ output (pin 23) of the μPB8228/8238 through a 1 K ohm series resistor, RESTART 7 will be gated onto the processor data bus when DBIN is active during an interrupt acknowledge machine cycle.

$\overline{\text{MEM/W}}$ and $\overline{\text{I/OW}}$ are generated by gating the $\overline{\text{WR}}$ signal from the processor with the contents of the status latch. $\overline{\text{I/OW}}$ indicates that an output port write is about to occur. $\overline{\text{MEM/W}}$ indicates that a memory write will occur.

The data bus output buffers and control signal buffers can be asynchronously forced into a high impedance state by placing a high on the $\overline{\text{BUSEN}}$ pin of the μPB8228/8238. Normal operation is performed with $\overline{\text{BUSEN}}$ low.

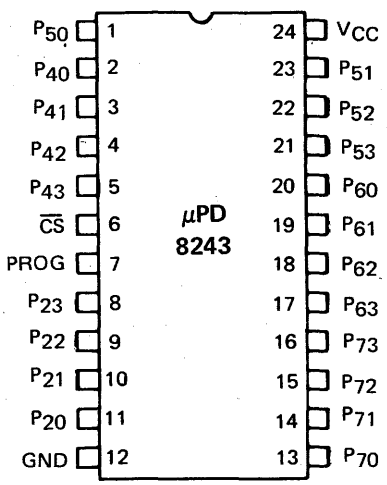
INPUT/OUTPUT EXPANDER FOR μPD8048/8748/8035

DESCRIPTION

The μPD8243 input/output expander is directly compatible with the μPD8048 family of single-chip microcomputers. Using NMOS technology the μPD8243 provides high drive capabilities while requiring only a single +5V supply voltage.



The μPD8243 interfaces to the μPD8048 family through a 4-bit I/O port and offers four 4-bit bi-directional static I/O ports. The ease of expansion allows for multiple μPD8243's to be added using the bus port.

The bi-directional I/O ports of the μPD8243 act as an extension of the I/O capabilities of the μPD8048 microcomputer family. They are accessible with their own ANL, MOV, and ORL instructions.

FEATURES

- Four 4-Bit I/O Ports
- Fully Compatible with μPD8048 Microcomputer Family
- High Output Drive
- NMOS Technology
- Single +5V Supply
- Direct Extension of Resident μPD8048 I/O Ports
- Logical AND and OR Directly to Ports
- Compatible with Industry Standard 8243
- Available in 24-Pin Plastic and Ceramic Packages

PIN CONFIGURATION

©IC MASTER 1979

FUNCTIONAL DESCRIPTION

General Operation

The I/O capabilities of the μPD8048/8748/8035 can be enhanced in four 4-bit I/O port increments using one or more μPD8243's. These additional I/O lines are addressed as ports 4-7. The following lists the operations which can be performed on ports 4-7.

- Logical AND Accumulator to Port.
- Logical OR Accumulator to Port.
- Transfer Port to Accumulator.
- Transfer Accumulator to Port.

Port 2 (P_{20}-P_{23}) forms the 4-bit bus through which the μPD8243 communicates with the host processor. The PROG output from the μPD8048/8748/8035 provides the necessary timing to the μPD8243. There are two 4-bit nibbles involved in each data transfer. The first nibble contains the op-code and port address followed by the second nibble containing the 4-bit data. Multiple μPD8243's can be used for additional I/O. The output lines from the μPD8048/8748/8035 can be used to form the chip selects for the additional μPD8243's.

Power On Initialization

Applying power to the μPD8243 sets ports 4-7 to the tri-state mode and port 2 to the input mode. The state of the PROG pin at power on may be either high or low. The PROG pin must make a high-to-low transition in order to exit from the power on mode. The power on sequence is initiated any time V_{CC} drops below 1V. The table below shows how the 4-bit nibbles on Port 2 correspond to the μPD8243 operations.

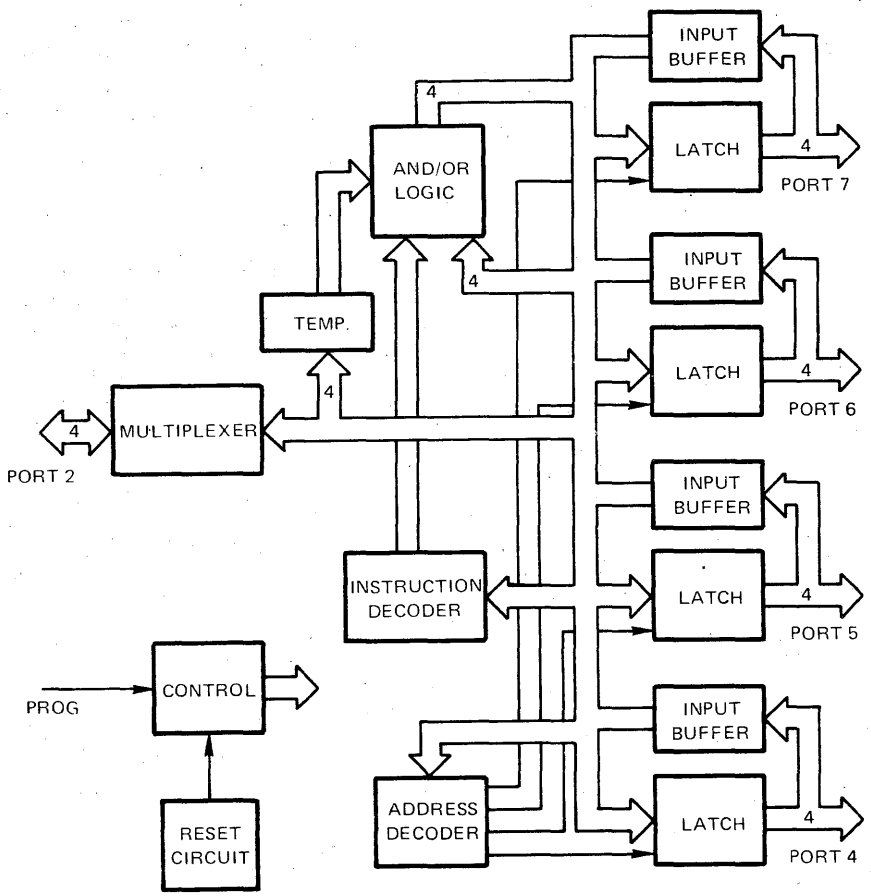
Port Address			Op-Code		
P_{21}	P_{20}	Address Code	P_{23}	P_{22}	Instruction Code
0	0	Port 4	0	0	Read
0	1	Port 5	0	1	Write
1	0	Port 6	1	0	ORLD
1	1	Port 7	1	1	ANLD

For example an 0010 appearing on P_{20}-P_{23}, respectively, would result in a Write to Port 4.

Read Mode

There is one Read mode in the μPD8243. A falling edge on the PROG pin latches the op-code and port address from input Port 2. The port address and Read operation are then decoded causing the appropriate outputs to be tri-stated and the input buffers switched on. The rising edge of PROG terminates the Read operation. The Port (4,5,6, or 7) that was selected by the Port address (P_{21}-P_{20}) is returned to the tri-state mode, and Port 2 is switched to the input mode.

Generally, in the read mode, a port will be an input and in the write mode it will be an output. If during program operation, the μPD8243's modes are changed, the first read pulse immediately following a write should be ignored. The subsequent read signals are valid. Reading a port will then force that port to a high impedance state.



Write Modes

There are three write modes in the μPD8243. The MOVD P_p,A instruction from the μPD8048/8748/8035 writes the new data directly to the specified port (4,5,6, or 7). The old data previously latched at that port is lost. The ORLD Pp,A instruction performs a logical OR between the new data and the data currently latched at the selected port. The result is then latched at that port. The final write mode uses the ANLD Pp,A instruction. It performs a logical AND between the new data and the data currently latched at the specified port. The result is latched at that port.

The data remains latched at the selected port following the logical manipulation until new data is written to that port.

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION
2-5 1, 21-23 17-20 13-16	P_{40}-P_{43} P_{50}-P_{53} P_{60}-P_{63} P_{70}-P_{73}	The four 4-bit static bi-directional I/O ports. They are programmable into the following modes: input mode (during a Read operation); low impedance latched output mode (after a Write operation); and the tri-state mode (following a Read operation). Data appearing on I/O lines P_{20}-P_{23} can be written directly. That data can also be logically ANDed or ORed with the previous data on those lines.
6	$\overline{CS}$	Chip Select input (active-low). When the μPD8343 is deselected ($\overline{CS}$ = 1), output or internal status changes are inhibited.
7	PROG	Clock input pin. The control and address information are present on port lines P_{20}-P_{23} when PROG makes a high-to-low transition. Data is present on port lines P_{20}-P_{23} when PROG makes a low-to-high transition.
8-11	P_{20}-P_{23}	P_{20}-P_{23} form a 4-bit bi-directional port. Refer to PROG function for contents of P_{20}-P_{23} at the rising and falling edges of PROG. Data from a selected port is present on P_{20}-P_{23} prior to the rising edge of PROG if during a Read operation.
12	GND	The μPD8041/8741 ground potential.
24	V_{CC}	+5 volt supply.

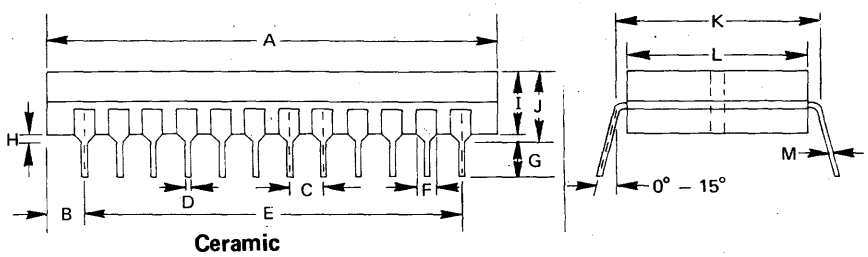
CURRENT SINKING CAPABILITY ①



Note: ① This curve plots the guaranteed worst case current sinking capability of any I/O port line versus the total sink current of all pins. The μPD8243 is capable of sinking 5 mA (for V_{OL} = 0.4V) through each of the 16 I/O lines simultaneously. The current sinking curve shows how the individual I/O line drive increases if all the I/O lines are not fully loaded.

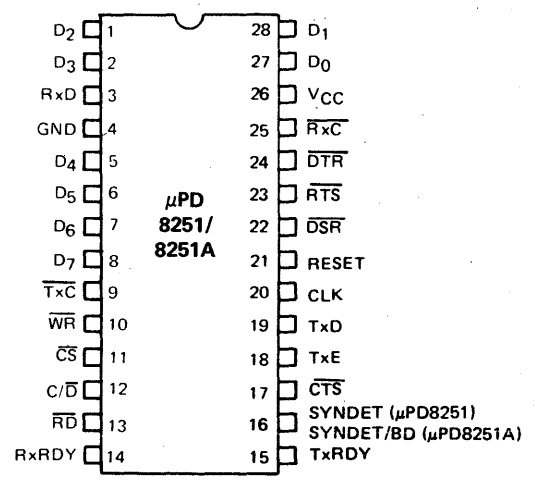
PROGRAMMABLE COMMUNICATION INTERFACES



DESCRIPTION

The μPD8251 and μPD8251A Universal Synchronous/Asynchronous Receiver/Transmitters (USARTs) are designed for microcomputer systems data communications. The USART is used as a peripheral and is programmed by the μPD8080 or other processor to communicate in commonly used serial data transmission techniques including IBM Bi-Sync. The USART receives serial data streams and converts them into parallel data characters for the processor. While receiving serial data, the USART will also accept data characters from the processor in parallel format, convert them to serial format and transmit. The USART will signal the processor when it has completely received or transmitted a character and requires service. Complete USART status including data format errors and control signals such as TxE and SYNDET, is available to the processor at any time.

FEATURES

- Asynchronous or Synchronous Operation
  - Asynchronous:
    - 5-8 Bit Characters
    - Clock Rate – 1, 16 or 64 x Baud Rate
    - Break Character Generation
    - Select 1, 1-1/2, or 2 Stop Bits
    - False Start Bit Detector
    - Automatic Break Detect and Handling (μPD8251A)
  - Synchronous:
    - 5-8 Bit Characters
    - Internal or External Character Synchronization
    - Automatic Sync Insertion
    - Single or Double Sync Characters
- Baud Rate – Synchronous – DC to 56K Baud (μPD8251)
  – DC to 64K Baud (μPD8251A)
  – Asynchronous – DC to 9.6K Baud
- Full Duplex, Double Buffered Transmitter and Receiver
- Parity, Overrun and Framing Flags
- Fully Compatible with 8080/8085/μPD780 (Z80™)
- All Inputs and Outputs are TTL Compatible
- Single +5 Volt Supply
- Separate Device, Receive and Transmit TTL Clocks
- 28 Pin Plastic DIP Package
- N-Channel MOS Technology

PIN CONFIGURATION

PIN NAMES

D_7-D_0	Data Bus (8 bits)
C/D	Control or Data is to be Written or Read
RD	Read Data Command
WR	Write Data or Control Command
CS	Chip Enable
CLK	Clock Pulse (TTL)
RESET	Reset
TxC	Transmitter Clock (TTL)
TxD	Transmitter Data
RxC	Receiver Clock (TTL)
RxD	Receiver Data
RxRDY	Receiver Ready (has character for 8080)
TxRDY	Transmitter Ready (ready for char. from 8080)
DSR	Data Set Ready
DTR	Data Terminal Ready
SYNDET	Sync Detect
SYNDET/BD	Sync Detect/Break Detect
RTS	Request to Send Data
CTS	Clear to Send Data
TxE	Transmitter Empty
VCC	+5 Volt Supply
GND	Ground

μPD8251/8251A

FUNCTIONAL DESCRIPTION

The μPD8251 and μPD8251A Universal Synchronous/Asynchronous Receiver/Transmitters are designed specifically for 8080 microcomputer systems but work with most 8-bit processors. Operation of the μPD8251 and μPD8251A, like other I/O devices in the 8080 family, are programmed by system software for maximum flexibility.

In the receive mode, the μPD8251 or μPD8251A converts incoming serial format data into parallel data and makes certain format checks. In the transmit mode, it formats parallel data into serial form. The device also supplies or removes characters or bits that are unique to the communication format in use. By performing conversion and formatting services automatically, the USART appears to the processor as a simple or "transparent" input or output of byte-oriented parallel data.

μPD8251A FEATURES AND ENHANCEMENTS

The μPD8251A is an advanced design of the industry standard 8251 USART. It operates with a wide range of microprocessors, including the 8080, 8085, and μPD780 (Z80™). The additional features and enhancements of the μPD8251A over the μPD8251 are listed below.

1. The data paths are double-buffered with separate I/O registers for control, status, Data In and Data Out. This feature simplifies control programming and minimizes processor overhead.
2. The Receiver detects and handles "break" automatically in asynchronous operations, which relieves the processor of this task.
3. The Receiver is prevented from starting when in "break" state by a refined Rx initialization. This also prevents a disconnected USART from causing unwanted interrupts.
4. When a transmission is concluded the TxD line will always return to the marking state unless SBRK is programmed.
5. The Tx Disable command is prevented from halting transmission by the Tx Enable Logic enhancement, until all data previously written has been transmitted. The same logic also prevents the transmitter from turning off in the middle of a word.
6. Internal Sync Detect is disabled when External Sync Detect is programmed. An External Sync Detect Status is provided through a flip-flop which clears itself upon a status read.
7. The possibility of a false sync detect is minimized by:
   - ensuring that if a double sync character is programmed, the characters be contiguously detected.
   - clearing the Rx register to all Logic 1s (V_{OH}) whenever the Enter Hunt command is issued in Sync mode.
8. The $\overline{RD}$ and $\overline{WR}$ do not affect the internal operation of the device as long as the μPD8251A is not selected.
9. The μPD8251A Status can be read at any time, however, the status update will be inhibited during status read.
10. The μPD8251A has enhanced AC and DC characteristics and is free from extraneous glitches, providing higher speed and improved operating margins.
11. Baud rate from DC to 64K.

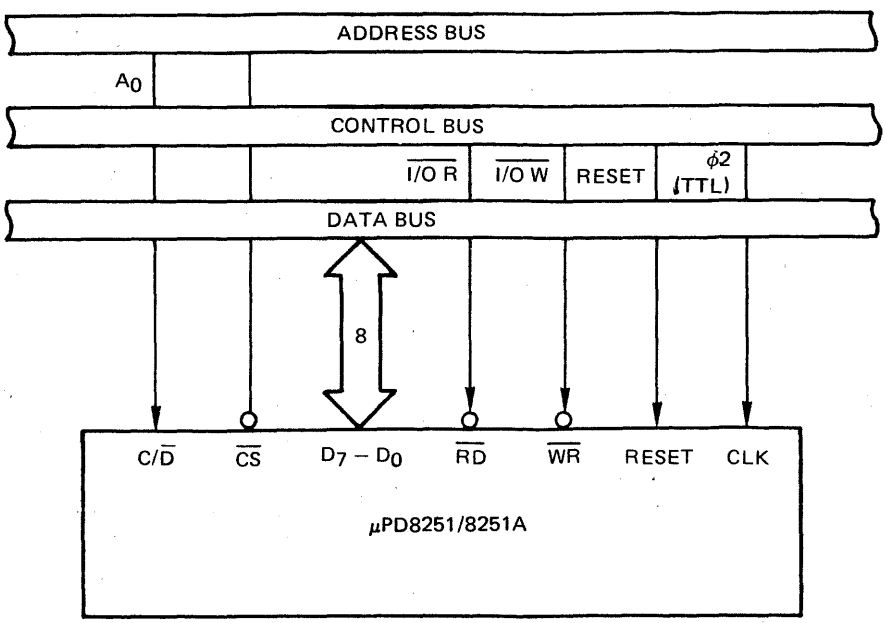
TEST LOAD CIRCUIT

©IC MASTER 1979



TRANSMIT BUFFER/ CONVERTER

The Transmit Buffer/Converter receives parallel data from the Data Bus Buffer via the internal data bus, converts parallel to serial data, inserts the necessary characters or bits needed for the programmed communication format and outputs composite serial data on the TxD output.

PIN IDENTIFICATION (CONT.)

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
Transmit Control Logic			The Transmit Control Logic accepts and outputs all external and internal signals necessary for serial data transmission.
15	TxRDY	Transmitter Ready	Transmitter Ready signals the processor that the transmitter is ready to accept a data character. TxRDY can be used as an interrupt or may be tested through the Status information for Polled operation. Loading a character from the processor automatically resets TxRDY.
18	TxE	Transmitter Empty	The Transmitter Empty output signals the processor that the USART has no further characters to transmit. TxE is automatically reset upon receiving a data character from the processor. In half-duplex, TxE can be used to signal end of a transmission and request the processor to "turn the line around." The TxEn bit in the command instruction does not effect TxE. In the Synchronous mode, a "one" on this output indicates that a Sync character or characters are about to be automatically transmitted as "fillers" because the next data character has not been loaded.
9	$\overline{TxC}$	Transmitter Clock	The Transmitter Clock controls the serial character transmission rate. In the Asynchronous mode, the $\overline{TxC}$ frequency is a multiple of the actual Baud Rate. Two bits of the Mode Instruction select the multiple to be 1x, 16x, or 64x the Baud Rate. In the Synchronous mode, the $\overline{TxC}$ frequency is automatically selected to equal the actual Baud Rate. Note that for both Synchronous and Asynchronous modes, serial data is shifted out of the USART by the falling edge of $\overline{TxC}$.
19	TxD	Transmitter Data	The Transmit Control Logic outputs the composite serial data stream on this pin.

μPD8251 AND μPD8251A INTERFACE TO 8080 STANDARD SYSTEM BUS

©IC MASTER 1979

RECEIVER BUFFER

The Receiver Buffer accepts serial data input at the $\overline{RxD}$ pin and converts the data from serial to parallel format. Bits or characters required for the specific communication technique in use are checked and then an eight-bit "assembled" character is readied for the processor. For communication techniques which require less than eight bits, the μPD8251 and μPD8251A sets the extra bits to "zero."

PIN IDENTIFICATION (CONT.)

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
Receiver Control Logic			This block manages all activities related to incoming data.
14	RxRDY	Receiver Ready	The Receiver Ready output indicates that the Receiver Buffer is ready with an "assembled" character for input to the processor. For Polled operation, the processor can check RxRDY using a Status Read or RxRDY can be connected to the processor interrupt structure. Note that reading the character to the processor automatically resets RxRDY.
25	$\overline{RxC}$	Receiver Clock	The Receiver Clock is the rate at which the incoming character is received. In the Asynchronous mode, the $\overline{RxC}$ frequency may be 1,16 or 64 times the actual Baud Rate but in the Synchronous mode the $\overline{RxC}$ frequency must equal the Baud Rate. Two bits in the mode instruction select Asynchronous at 1x, 16x or 64x or Synchronous operation at 1x the Baud Rate. Unlike $\overline{TxC}$, data is sampled by the μPD8251 and μPD8251A on the rising edge of $\overline{RxC}$. ①
3	RxD	Receiver Data	A composite serial data stream is received by the Receiver Control Logic on this pin.
16	SYNDET (μPD8251)	Sync Detect	The SYNC Detect pin is only used in the Synchronous mode. The μPD8251 may be programmed through the Mode Instruction to operate in either the internal or external Sync mode and SYNDET then functions as an output or input respectively. In the internal Sync mode, the SYNDET output will go to a "one" when the μPD8251 has located the SYNC character in the Receive mode. If double SYNC character (bi-sync) operation has been programmed, SYNDET will go to "one" in the middle of the last bit of the second SYNC character. SYNDET is automatically reset to "zero" upon a Status Read or RESET. In the external SYNC mode, a "zero" to "one" transition on the SYNDET input will cause the μPD8251 to start assembling data character on the next falling edge of $\overline{RxC}$. The length of the SYNDET input should be at least one $\overline{RxC}$ period, but may be removed once the μPD8251 is in SYNC.
16	SYNDET/BD (μPD8251A)	Sync Detect/ Break Detect	The SYNDET/BD pin is used in both Synchronous and Asynchronous modes. When in SYNC mode the features for the SYNDET pin described above apply. When in Asynchronous mode, the Break Detect output will go high when an all zero word of the programmed length is received. This word consists of: start bit, data bit, parity bit and one stop bit. Reset only occurs when Rx data returns to a logic one state or upon chip reset. The state of Break Detect can be read as a status bit.

Note: ① Since the μPD8251 and μPD8251A will frequently be handling both the reception and transmission for a given link, the Receive and Transmit Baud Rates will be same. $\overline{RxC}$ and $\overline{TxC}$ then require the same frequency and may be tied together and connected to a single clock source or Baud Rate Generator.

Examples:

If the Baud Rate equals 110 (Async):
- $\overline{RxC}$ or $\overline{TxC}$ equals 110 Hz (1x)
- $\overline{RxC}$ or $\overline{TxC}$ equals 1.76 KHz (16x)
- $\overline{RxC}$ or $\overline{TxC}$ equals 7.04 KHz (64x)

If the Baud Rate equals 300:
- $\overline{RxC}$ or $\overline{TxC}$ equals 300 Hz (1x) A or S
- $\overline{RxC}$ or $\overline{TxC}$ equals 4800 Hz (16x) A only
- $\overline{RxC}$ or $\overline{TxC}$ equals 19.2 KHz (64x) A only

©IC MASTER 1979

OPERATIONAL DESCRIPTION

A set of control words must be sent to the μPD8251 and μPD8251A to define the desired mode and communications format. The control words will specify the BAUD RATE FACTOR (1x, 16x, 64x), CHARACTER LENGTH (5 to 8), NUMBER OF STOP BITS (1, 1-1/2, 2) ASYNCHRONOUS or SYNCHRONOUS MODE, SYNDET (IN or OUT), PARITY, etc.

After receiving the control words, the μPD8251 and μPD8251A are ready to communicate. TxRDY is raised to signal the processor that the USART is ready to receive a character for transmission. When the processor writes a character to the USART, TxRDY is automatically reset.

Concurrently, the μPD8251 and μPD8251A may receive serial data; and after receiving an entire character, the RxRDY output is raised to indicate a completed character is ready for the processor. The processor fetch will automatically reset RxRDY.

Note: The μPD8251 and μPD8251A may provide faulty RxRDY for the first read after power-on or for the first read after receive is re-enabled by a command instruction (RxE). A dummy read is recommended to clear faulty RxRDY. But this is not the case for the first read after hardware or software reset after the device operation has once been established.

The μPD8251 and μPD8251A cannot transmit until the TxEN (Transmitter Enable) bit has been set by a Command Instruction and until the $\overline{CTS}$ (Clear to Send) input is a "zero". TxD is held in the "marking" state after Reset awaiting new Command Words.

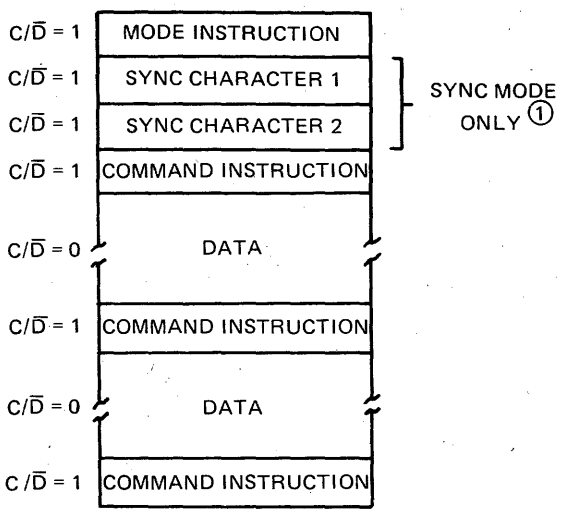
μPD8251 PROGRAMMING

The USART must be loaded with a group of two to four control words provided by the processor before data reception and transmission can begin. A Reset (internal or external) must immediately proceed the control words which are used to program the complete operational description of the communications interface. If an external RESET is not available, three successive 00 Hex or two successive 80 Hex command instructions ($C/\overline{D}$ = 1) followed by a software reset command instruction (40 Hex) can be used to initialize the μPD8251 and μPD8251A.

There are two control word formats:

1. Mode Instruction
2. Command Instruction

MODE INSTRUCTION



This control word specifies the general characteristics of the interface regarding the SYNCHRONOUS or ASYNCHRONOUS MODE, BAUD RATE FACTOR, CHARACTER LENGTH, PARITY, and NUMBER OF STOP BITS. Once the Mode Instruction has been received, SYNC characters or Command Instructions may be inserted depending on the Mode Instruction content.

COMMAND INSTRUCTION

This control word will be interpreted as a SYNC character definition if immediately preceded by a Mode Instruction which specified a Synchronous format. After the SYNC character(s) are specified or after an Asynchronous Mode Instruction, all subsequent control words will be interpreted as an update to the Command Instruction. Command Instruction updates may occur at any time during the data block. To modify the Mode Instruction, a bit may be set in the Command Instruction which causes an internal Reset which allows a new Mode Instruction to be accepted.

©IC MASTER 1979

TYPICAL DATA BLOCK

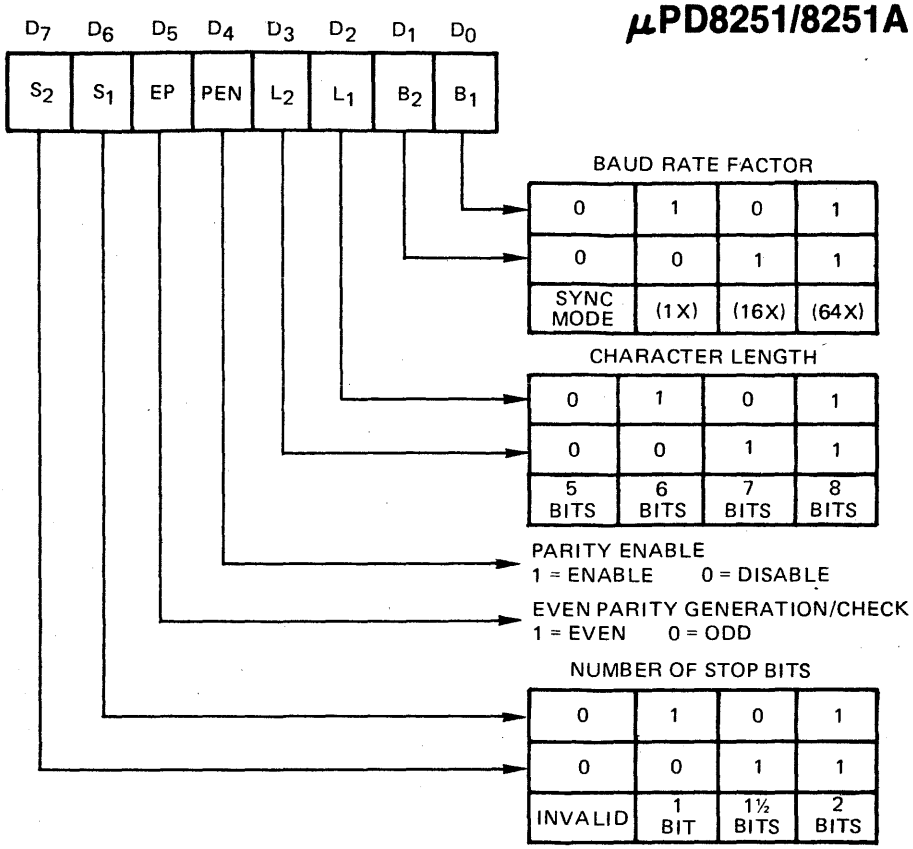
NOTE (1) The second SYNC character is skipped if MODE instruction has programmed the μPD8251 and μPD8251A to single character Internal SYNC Mode. Both SYNC characters are skipped if MODE instruction has programmed the μPD8251 and μPD8251A to ASYNC mode.

MODE INSTRUCTION DEFINITION

The μPD8251 and μPD8251A can operate in either Asynchronous or Synchronous communication modes. Understanding how the Mode Instruction controls the functional operation of the USART is easiest when the device is considered to be two separate components, one asynchronous and the other synchronous, which share the same support circuits and package. Although the format definition can be changed at will or "on the fly", the two modes will be explained separately for clarity.

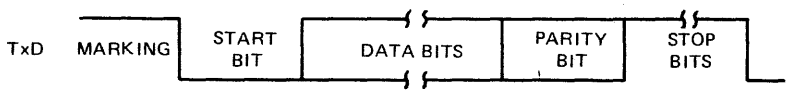
ASYNCHRONOUS TRANSMISSION

When a data character is written into the μPD8251 and μPD8251A, the USART automatically adds a START bit (low level or "space") and the number of STOP bits (high level or "mark") specified by the Mode Instruction. If Parity has been enabled, an odd or even Parity bit is inserted just before the STOP bit(s), as specified by the Mode Instruction. Then, depending on $\overline{CTS}$ and TxEN, the character may be transmitted as a serial data stream at the TxD output. Data is shifted out by the falling edge of $\overline{TxC}$ at $\overline{TxC}$, $\overline{TxC}$/16 or $\overline{TxC}$/64, as defined by the Mode Instruction.



If no data characters have been loaded into the μPD8251 and μPD8251A, or if all available characters have been transmitted, the TxD output remains "high" (marking) in preparation for sending the START bit of the next character provided by the processor. TxD may be forced to send a BREAK (continuously low) by setting the correct bit in the Command Instruction.

ASYNCHRONOUS RECEIVE



The RxD input line is normally held "high" (marking) by the transmitting device. A falling edge at RxD signals the possible beginning of a START bit and a new character. The START bit is checked by testing for a "low" at its nominal center as specified by the BAUD RATE. If a "low" is detected again, it is considered valid, and the bit assembling counter starts counting. The bit counter locates the approximate center of the date, parity (if specified), and STOP bits. The parity error flag (PE) is set, if a parity error occurs. Input bits are sampled at the RxD pin with the rising edge of $\overline{RxC}$. If a high is not detected for the STOP bit, which normally signals the end of an input character, a framing error (FE) will be set. After a valid STOP bit, the input character is loaded into the parallel Data Bus Buffer of the μPD8251 and μPD8251A and the RxRDY signal is raised to indicate to the processor that a character is ready to be fetched. If the processor has failed to fetch the previous character, the new character replaces the old and the overrun flag (OE) is set. All the error flags can be reset by setting a bit in the Command Instruction. Error flag conditions will not stop subsequent USART operation.

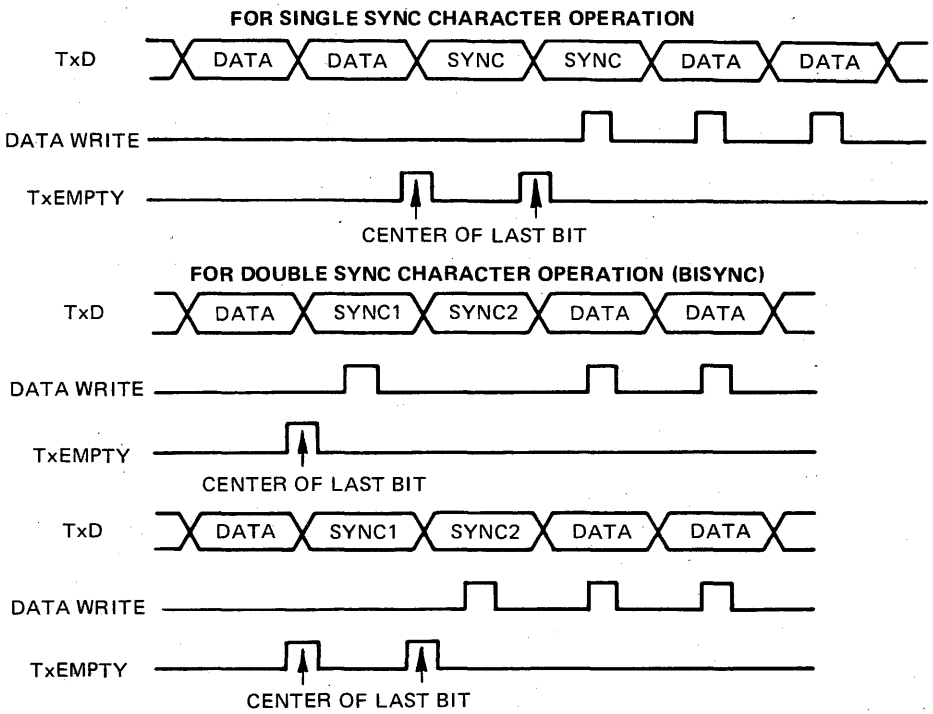
TRANSMITTER OUTPUT

RECEIVER INPUT

TRANSMISSION FORMAT

NOTE ①: IF CHARACTER LENGTH IS DEFINED AS 5, 6, OR 7 BITS; THE UNUSED BITS ARE SET TO "ZERO."

RECEIVE FORMAT



©IC MASTER 1979

SYNCHRONOUS TRANSMISSION

As in Asynchronous transmission, the TxD output remains "high" (marking) until the μPD8251 and μPD8251A receive the first character from the processor which is usually a SYNC character. After a Command Instruction has set TxEN and after Clear to Send ($\overline{CTS}$) goes low, the first character is serially transmitted. Data is shifted out on the falling edge of $\overline{TxC}$ and the same rate as $\overline{TxC}$.

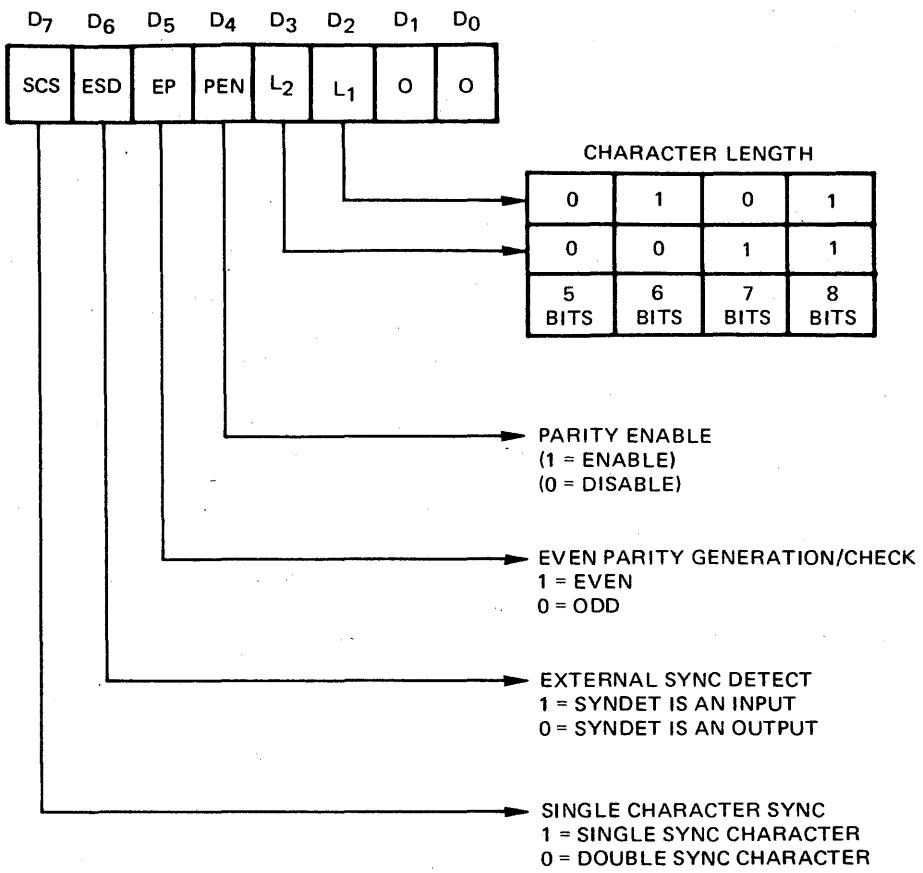
Once transmission has started, Synchronous Mode format requires that the serial data stream at TxD continue at the $\overline{TxC}$ rate or SYNC will be lost. If a data character is not provided by the processor before the μPD8251 and μPD8251A Transmitter Buffer becomes empty, the SYNC character(s) loaded directly following the Mode Instruction will be automatically inserted in the TxD data stream. The SYNC character(s) are inserted to fill the line and maintain synchronization until new data characters are available for transmission. If the μPD8251 and μPD8251A become empty, and must send the SYNC character(s), the TxEMPTY output is raised to signal the processor that the Transmitter Buffer is empty and SYNC characters are being transmitted. TxEMPTY is automatically reset by the next character from the processor.

TxEMPTY go high at the middle of the last data bit when the Transmit Register is EMPTY. TxEMPTY goes low again as sync characters are transmitted. See figure below.

SYNCHRONOUS RECEIVE

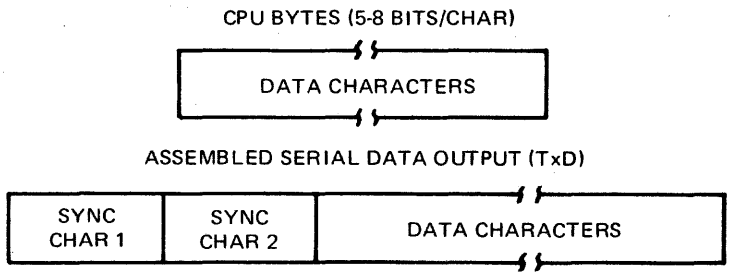
In Synchronous Receive, character synchronization can be either external or internal. If the internal SYNC mode has been selected, and the Enter HUNT (EH) bit has been set by a Command Instruction, the receiver goes into the HUNT mode.

Incoming data on the RxD input is sampled on the rising edge of $\overline{RxC}$, and the Receiver Buffer is compared with the first SYNC character after each bit has been loaded until a match is found. If two SYNC characters have been programmed, the next received character is also compared. When the SYNC character(s) programmed have been detected, the μPD8251 and μPD8251A leave the HUNT mode and are in character synchronization. At this time, the SYNDET (output) is set high. SYNDET is automatically reset by a STATUS READ.



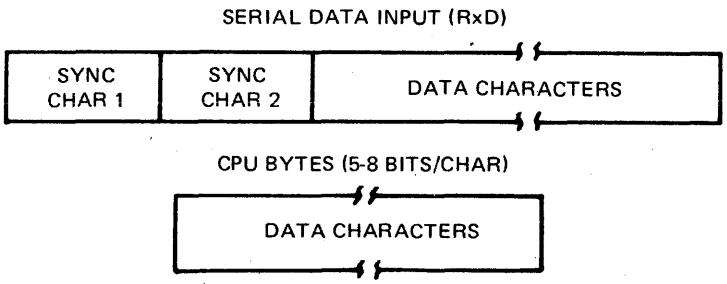
If external SYNC has been specified in the Mode Instruction, a "one" applied to the SYNDET (input) for at least one $\overline{RxC}$ cycle will synchronize the USART.

Parity and Overrun Errors are treated the same in the Synchronous as in the Asynchronous Mode. Framing errors do not apply in the Synchronous format.



The processor may command the receiver to enter the HUNT mode with a Command Instruction which sets Enter HUNT (EH) if synchronization is lost.

©IC MASTER 1979



MODE INSTRUCTION FORMAT SYNCHRONOUS MODE

TRANSMIT/RECEIVE FORMAT SYNCHRONOUS MODE

TRANSMIT FORMAT

RECEIVE FORMAT

©IC MASTER 1979

COMMAND INSTRUCTION FORMAT

After the functional definition of the μPD8251 and μPD8251A has been specified by the Mode Instruction and the SYNC character(s) have been entered, if in SYNC mode, the USART is ready to receive Command Instructions and begin communication. A Command Instruction is used to control the specific operation of the format selected by the Mode Instruction. Enable Transmit, Enable Receive, Error Reset and Modem Controls are controlled by the Command Instruction.

After the Mode Instruction and the SYNC character(s), as needed, are loaded, all subsequent "control writes" ($C/\overline{D} = 1$) will load or overwrite the Command Instruction register. A Reset operation (internal via CMD IR or external via the RESET input) will cause the μPD8251 and μPD8251A to interpret the next "control write", which must immediately follow the reset, as a Mode Instruction.

STATUS READ FORMAT

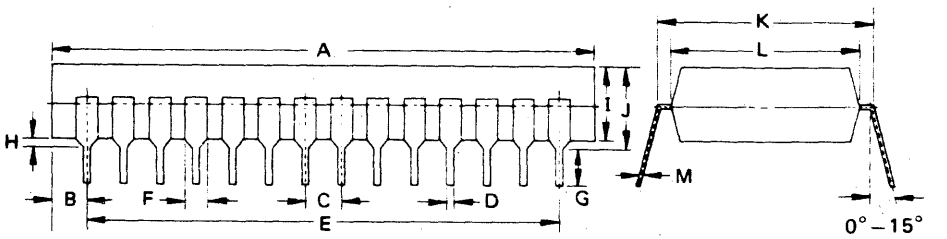
It is frequently necessary for the processor to examine the "status" of an active interface device to determine if errors have occurred or to notice other conditions which require a response from the processor. The μPD8251 and μPD8251A have features which allow the processor to "read" the device status at any time. A data fetch is issued by the processor while holding the $C/\overline{D}$ input "high" to obtain device Status Information. Many of the bits in the status register are copies of external pins. This dual status arrangement allows the μPD8251 and μPD8251A to be used in both Polled and interrupt driven environments. Status update can have a maximum delay of a 16 clock period.

PARITY ERROR

When a parity error is detected, the PE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. PE being set does not inhibit USART operation.

OVERRUN ERROR

If the processor fails to read a data character before the one following is available, the OE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. Although OE being set does not inhibit USART operation, the previously received character is overwritten and lost.



FRAMING ERROR①

If a valid STOP bit is not detected at the end of a character, the FE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. FE being set does not inhibit USART operation.

Note: ① ASYNC mode only.

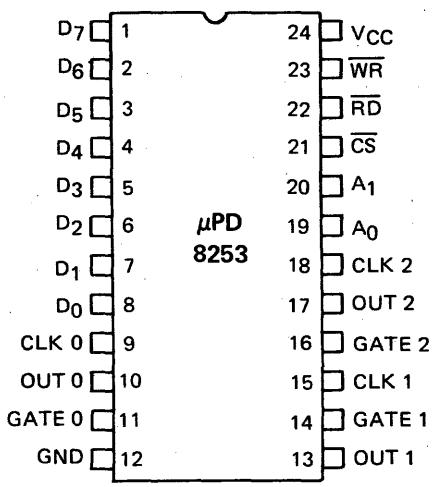
PROGRAMMABLE INTERVAL TIMER

DESCRIPTION

The NEC μPD8253 contains three independent, programmable, multi-modal 16-bit counter/timers. It is designed as a general purpose device, fully compatible with the 8080 family. The μPD8253 interfaces directly to the busses of the processor as an array of I/O ports.

The μPD8253 can generate accurate time delays under the control of system software. The three independent 16-bit counters can be clocked at rates from DC to 2 MHz. The system software controls the loading and starting of the counters to provide accurate multiple time delays. The counter output flags the processor at the completion of the time-out cycles.



System overhead is greatly improved by relieving the software from the maintenance of timing loops. Some other common uses for the μPD8253 in microprocessor based systems are:

- Programmable Baud Rate Generator
- Event Counter
- Binary Rate Multiplier
- Real Time Clock
- Digital One-Shot
- Complex Motor Controller

FEATURES

- Three Indpendent 16-Bit Counters
- Clock Rate: DC to 3 MHz
- Programmable Counter Modes
- Count Binary or BCD
- Single +5 Volt Supply
- 24 Pin Dual-In-Line Plastic Package

PIN CONFIGURATION

PIN NAMES

D_7-D_0	Data Bus (8-Bit)
CLK N	Counter Clock Inputs
GATE N	Counter Gate Inputs

FUNCTIONAL DESCRIPTION

Data Bus Buffer

The 3-state, 8-bit, bi-directional Data Bus Buffer interfaces the μPD8253 to the 8080A microprocessor system. It will transmit or receive data in accordance with the INput or OUTput instructions executed by the processor. There are three basic functions of the Data Bus Buffer.

1. Program the modes of the μPD8253
2. Load the count registers.
3. Read the count values.

Read/Write Logic

The Read/Write Logic controls the overall operation of the μPD8253 and is governed by inputs received from the processor system bus.

Control Word Register

Two bits from the address bus of the processor, A_0 and A_1, select the Control Word Register when both are at a logic "1" (active-high logic). When selected, the Control Word Register stores data from the Data Bus Buffer in a register. This data is then used to control:

1. The operational MODE of the counters.
2. The selection of BCD or Binary counting.
3. The loading of the count registers.

$\overline{RD}$ (Read)

This active-low signal instructs the μPD8253 to transmit the selected counter value to the processor.

$\overline{WR}$ (Write)

This active-low signal instructs the μPD8253 to receive MODE information or counter input data from the processor.

A_1, A_0

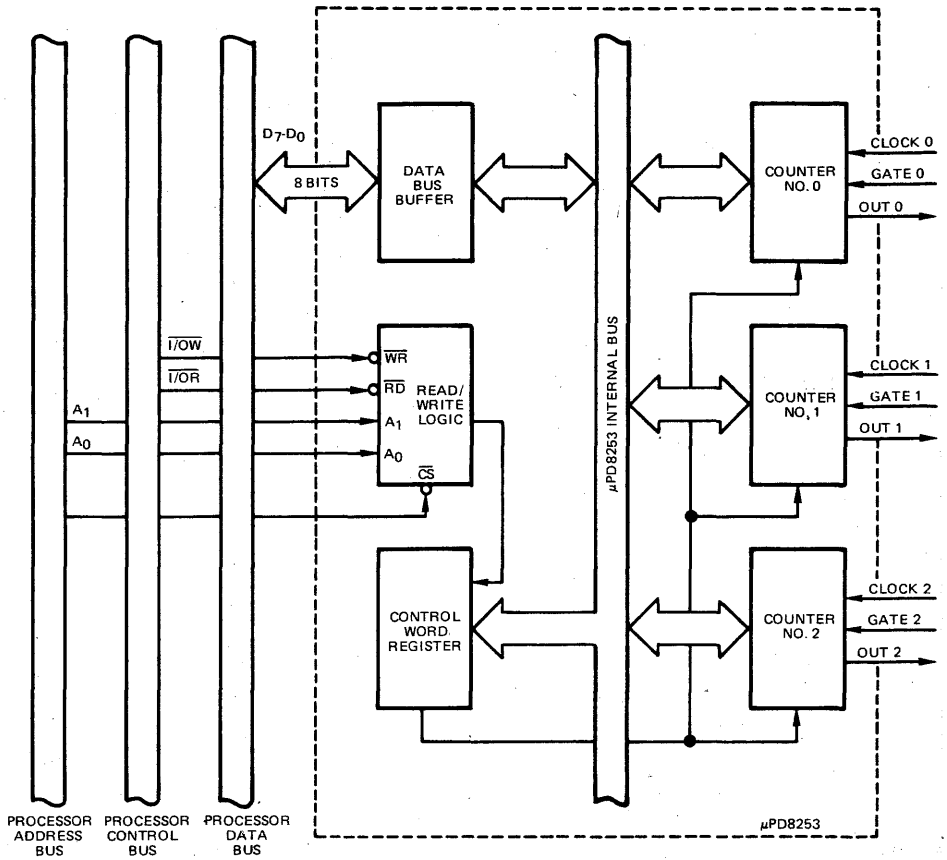
The A_1 and A_0 inputs are normally connected to the address bus of the processor. They control the one-of-three counter selection and address the control word register to select one of the six operational MODES.

$\overline{CS}$ (Chip Select)

The μPD8253 is enabled when an active-low signal is applied to this input. Reading or writing from this device is inhibited when the chip is disabled. The counter operation, however, is not affected.

Counters #0, #1, #2

The three identical, 16-bit down counters are functionally independent allowing for separate MODE configuration and counting operation. They function as Binary or BCD counters with their gate, input and output line configuration determined by the operational MODE data stored in the Control Word Register. The system software overhead time can be reduced by allowing the control word to govern the loading of the count data.



The programmer, with READ operations, has access to each counter's contents. The μPD8253 contains the commands and logic to read each counter's contents while still counting without disturbing its operation.

The following is a table showing how the counters are manipulated by the input signals to the Read/Write Logic.

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	A_1	A_0	FUNCTION
0	1	0	0	0	Load Counter No. 0
0	1	0	0	1	Load Counter No. 1
0	1	0	1	0	Load Counter No. 2
0	1	0	1	1	Write Mode Word

PROGRAMMING THE μPD8253

The programmer can select any of the six operational MODES for the counters using system software. Individual counter programming is accomplished by loading the CONTROL WORD REGISTER with the appropriate control word data (A_0, A_1 = 11).

CONTROL WORD FORMAT

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
SC1	SC0	RL1	RL0	M2	M1	M0	BCD

SC – Select Counter

SC1	SC0	
0	0	Select Counter 0
0	1	Select Counter 1
1	0	Select Counter 2
1	1	Invalid

RL – Read/Load

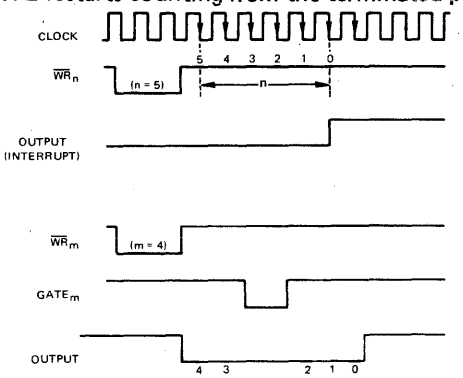
RL1	RL0	
0	0	Counter Latching Operation
1	0	Read/Load Most Significant Byte Only
0	1	Read/Load Least Significant Byte Only
1	1	Read/Load Least Significant Byte First, Then Most Significant Byte

BCD

0	Binary Counter, 16-Bits
1	BCD Counter, 4-Decades

M-Mode

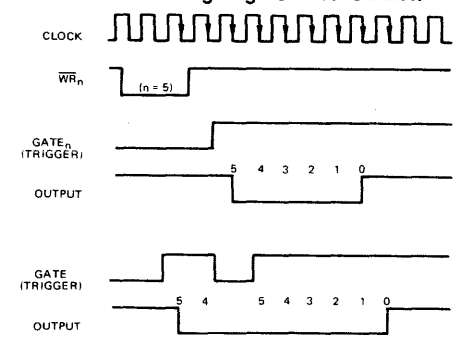
M2	M1	M0	
0	0	0	Mode 0
0	0	1	Mode 1
X	1	0	Mode 2
X	1	1	Mode 3
1	0	0	Mode 4
1	0	1	Mode 5



©IC MASTER 1979

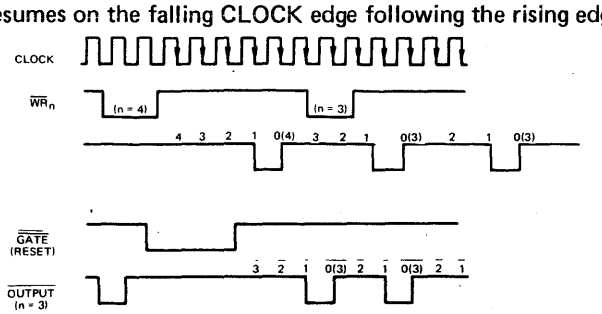
OPERATIONAL MODES ①

Each of the three counters can be individually programmed with different operating MODES by appropriately formatted Control Words. The following is a summary of the MODE operations.



Mode 0: Interrupt on Terminal Count

The initial MODE set operation forces the OUTPUT low. When the specified counter is loaded with the count value, it will begin counting. The OUTPUT will remain low until the terminal count sets it high. It will remain in the high state until the trailing edge of the second $\overline{WR}$ pulse loads in COUNT data. If data is loaded during the counting process, the first $\overline{WR}$ stops the count. Counting starts with the new count data triggered by the falling clock edge after the second $\overline{WR}$. If a GATE pulse is asserted while counting, the count is terminated for the duration of GATE. The falling edge of CLK following the removal of GATE restarts counting from the terminated point.



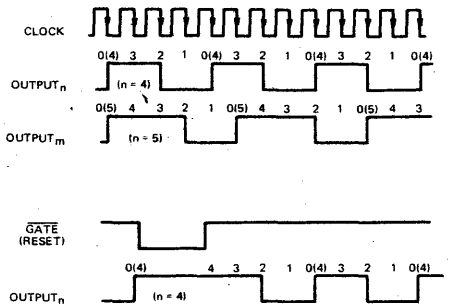
Mode 1: Programmable One-Shot

The OUTPUT is set low by the falling edge of CLOCK following the trailing edge of GATE. The OUTPUT is set high again at the terminal count. The output pulse is not affected if new count data is loaded while the OUTPUT is low. The new data will be loaded on the rising edge of the next trigger pulse. The assertion of a trigger pulse while OUTPUT is low, resets and retriggers the One-Shot. The OUTPUT will remain low for the full count value after the rising edge of TRIGGER.

Mode 2: Rate Generator

The RATE GENERATOR is a variable modulus counter. The OUTPUT goes low for one full CLOCK period as shown in following timing diagram. The count data sets the time between OUTPUT pulses. If the count register is reloaded between output pulses the present period will not be affected. The subsequent period will reflect the new value. The OUTPUT will remain high for the duration of the asserted GATE input. Normal operation resumes on the falling CLOCK edge following the rising edge of GATE.

Note: ① All internal counter events occur at the falling edge of the associated clock in all modes of operation.

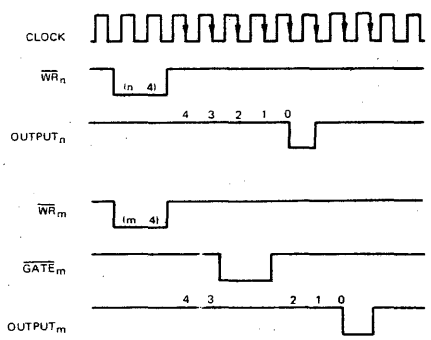


©IC MASTER 1979

OPERATIONAL MODES (Cont.) ①

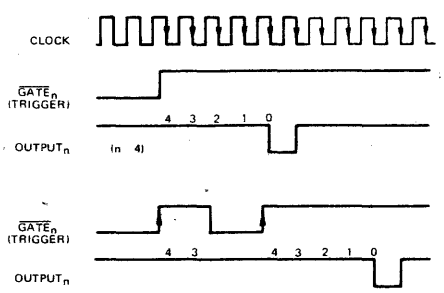
Mode 3: Square Wave Generator

MODE 3 resembles MODE 2 except the OUTPUT will be high for half of the count and low for the other half (for even values of data). For odd values of count data the OUTPUT will be high one clock cycle longer than when it is low (High Period → $\frac{N+1}{2}$ clock cycles; Low Period → $\frac{N-1}{2}$ clock periods, where N is the decimal value of count data). If the count register is reloaded with a new value during counting, the new value will be reflected immediately after the output transition of the current count.



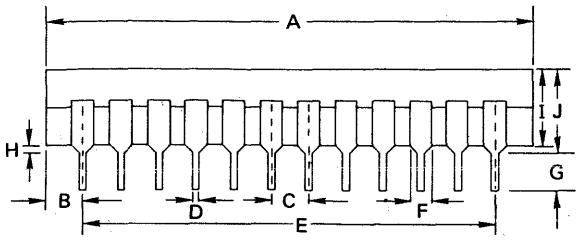
The OUTPUT will be held in the high state while GATE is asserted. Counting will start from the full count data after the GATE has been removed.

Mode 4: Software Triggered Strobe

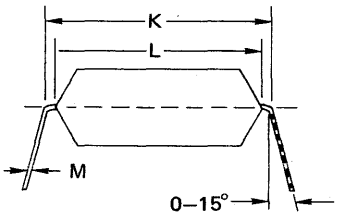


The OUTPUT goes high when MODE 4 is set, and counting begins after the second byte of data has been loaded. When the terminal count is reached, the OUTPUT will pulse low for one clock period. Changes in count data are reflected in the OUTPUT as soon as the new data has been loaded into the count registers. During the loading of new data, the OUTPUT is held high and counting is inhibited.

The OUTPUT is held high for the duration of GATE. The counters are reset and counting begins from the full data value after GATE is removed.



Mode 5: Hardware Triggered Strobe



Loading MODE 5 sets OUTPUT high. Counting begins when count data is loaded and GATE goes high. After terminal count is reached, the OUTPUT will pulse low for one clock period. Subsequent trigger pulses will restart the counting sequence with the OUTPUT pulsing low on terminal count following the last rising edge of the trigger input (Reference bottom half of timing diagram).

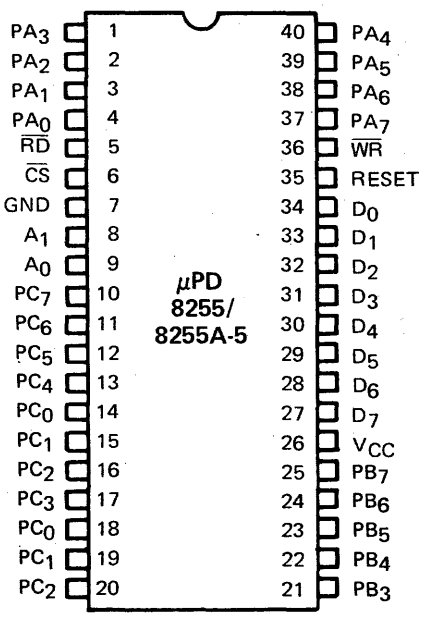
μPD8255
μPD8255A-5*

PROGRAMMABLE PERIPHERAL INTERFACES



DESCRIPTION

The μPD8255 and μPD8255A-5 are general purpose programmable INPUT/OUTPUT devices designed for use with the 8080A/8085A microprocessors. Twenty-four (24) I/O lines may be programmed in two groups of twelve (group I and group II) and used in three modes of operation. In the Basic mode, (MODE 0), each group of twelve I/O pins may be programmed in sets of 4 to be input or output. In the Strobed mode, (MODE 1), each group may be programmed to have 8 lines of input or output. Three of the remaining four pins in each group are used for handshaking strobes and interrupt control signals. The Bidirectional Bus mode, (MODE 2), uses the 8 lines of Port A for a bidirectional bus, and five lines from Port C for bus control signals. The μPD8255 and μPD8255A-5 are packaged in 40 pin plastic dual-in-line packages.

FEATURES

- Fully Compatible with the 8080A/8085 Microprocessor Families
- All Inputs and Outputs TTL Compatible
- 24 Programmable I/O Pins
- Direct Bit SET/RESET Eases Control Application Interfaces
- 8 – 2 mA Darlington Drive Outputs for Printers and Displays (μPD8255)
- 8 – 4 mA Darlington Drive Outputs for Printers and Displays (μPD8255A-5)
- LSI Drastically Reduces System Package Count
- Standard 40 Pin Dual-In-Line Plastic Package

PIN CONFIGURATION

FUNCTIONAL DESCRIPTION

General

The μPD8255 and μPD8255A-5 Programmable Peripheral Interfaces (PPI) are designed for use in 8080A/8085A microprocessor systems. Peripheral equipment can be effectively and efficiently interfaced to the 8080A/8085A data and control busses with the μPD8255 and μPD8255A-5. The μPD8255 and μPD8255A-5 are functionally configured to be programmed by system software to avoid external logic for peripheral interfaces.

Data Bus Buffer

The 3-state, bidirectional, eight bit Data Bus Buffer (D_0-D_7) of the μPD8255 and μPD8255A-5 can be directly interfaced to the processor's system Data Bus (D_0-D_7). The Data Bus Buffer is controlled by execution of IN and OUT instructions by the processor. Control Words and Status information are also transmitted via the Data Bus Buffer.

Read/Write and Control Logic

This block manages all of the internal and external transfers of Data, Control and Status. Through this block, the processor Address and Control busses can control the peripheral interfaces.

Chip Select, $\overline{CS}$, pin 6

A Logic Low, V_{IL}, on this input enables the μPD8255 and μPD8255A-5 for communication with the 8080A/8085A.

Read, $\overline{RD}$, pin 5

A Logic Low, V_{IL}, on this input enables the μPD8255 and μPD8255A-5 to send Data or Status to the processor via the Data Bus Buffer.

Write, $\overline{WR}$, pin 36

A Logic Low, V_{IL}, on this input enables the Data Bus Buffer to receive Data or Control Words from the processor.

Port Select 0, A_0, pin 9

Port Select 1, A_1, pin 8

These two inputs are used in conjunction with $\overline{CS}$, $\overline{RD}$, and $\overline{WR}$ to control the selection of one of three ports on the Control Word Register. A_0 and A_1 are usually connected to A_0 and A_1 of the processor Address Bus.

Reset, pin 35

A Logic High, V_{IH}, on this input clears the Control Register and sets ports A, B, and C to the input mode. The input latches in ports A, B, and C are not cleared.

Group I and Group II Controls

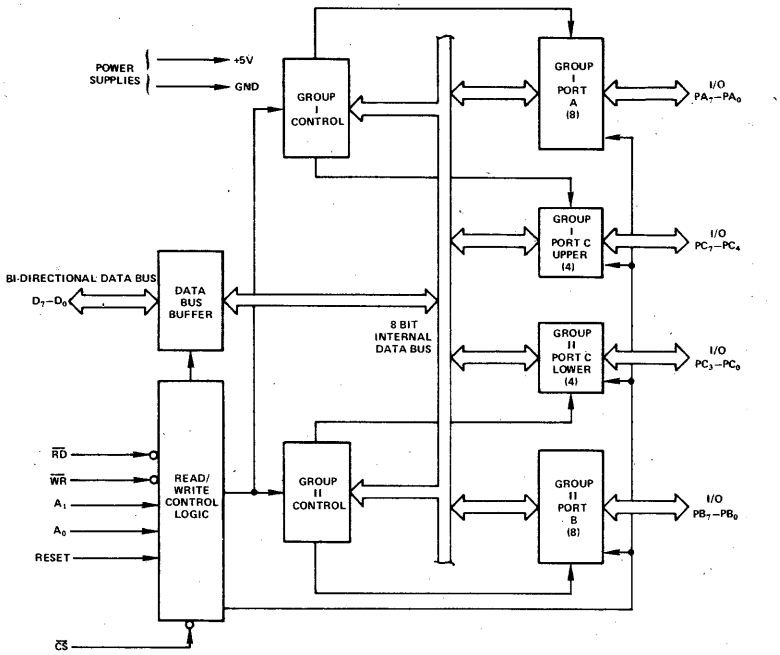
Through an OUT instruction in System Software from the processor, a control word is transmitted to the μPD8255 and μPD8255A-5. Information such as "MODE," "Bit SET," and "Bit RESET" is used to initialize the functional configuration of each I/O port.

Each group (I and II) accepts "commands" from the Read/Write Control Logic and "control words" from the internal data bus and in turn controls its associated I/O ports.

Group I — Port A and upper Port C (PC_7-PC_4)
Group II — Port B and lower Port C (PC_3-PC_0)

While the Control Word Register can be written into, the contents cannot be read back to the processor.

Ports A, B, and C



The three 8-bit I/O ports (A, B, and C) in the μPD8255 and μPD8255A-5 can all be configured to meet a wide variety of functional requirements through system software. The effectiveness and flexibility of the μPD8255 and μPD8255A-5 is further enhanced by special features unique to each of the ports.

Port A = An 8-bit data output latch/buffer and data input latch.
Port B = An 8-bit data input/output latch/buffer and an 8-bit data input buffer.
Port C = An 8-bit output latch/buffer and a data input buffer (input not latched).

Port C may be divided into two independent 4-bit control and status ports for use with Ports A and B.

μPD8255/8255A-5

MODES

The μPD8255 and μPD8255A-5 can be operated in modes (0, 1 or 2) which are selected by appropriate control words and are detailed below.

MODE 0

- MODE 0 provides for basic Input and Output operations through each of the ports A, B, and C. Output data is latched and input data follows the peripheral. No "handshaking" strobes are needed.

  16 different configurations in MODE 0

  Two 8-bit ports and two 4-bit ports

  Inputs are not latched

  Outputs are latched

MODE 1

MODE 1 provides for Strobed Input and Output operations with data transferred through Port A or B and handshaking through Port C.

Two I/O Groups (I and II)

Both groups contain an 8-bit data port and a 4-bit control/data port

Both 8-bit data ports can be either Latched Input or Latched Output

MODE 2

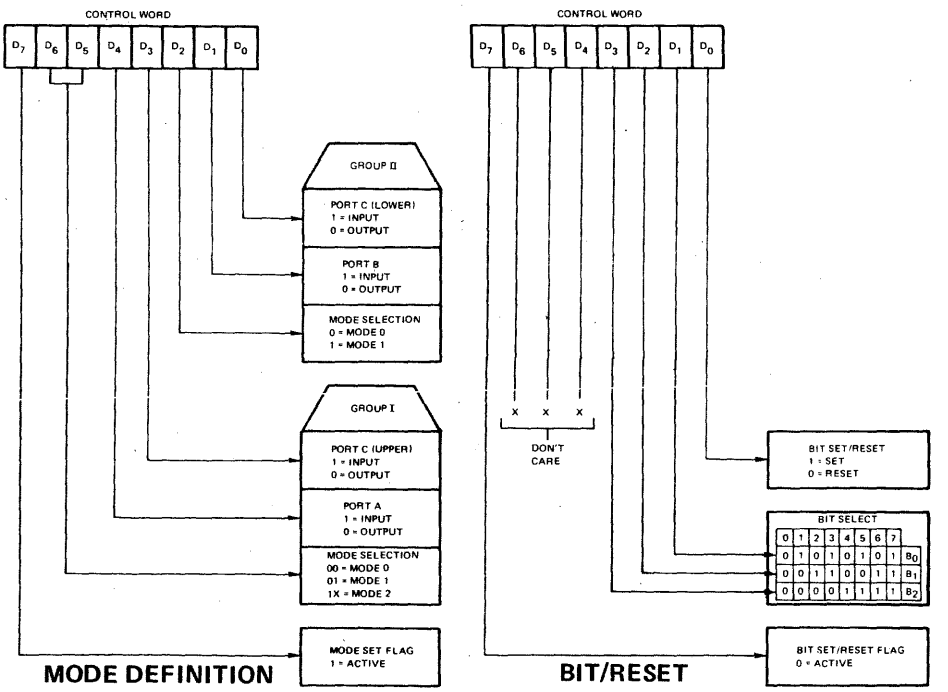
MODE 2 provides for Strobed bidirectional operation using PA_{0-7} as the bidirectional latched data bus. PC_{3-7} is used for interrupts and "handshaking" bus flow controls similar to Mode 1. Note that PB_{0-7} and PC_{0-2} may be defined as Mode 0 or 1, input or output in conjunction with Port A in Mode 2.

An 8-bit latched bidirectional bus port (PA_{0-7}) and a 5-bit control port (PC_{3-7})

Both inputs and outputs are latched

An additional 8-bit input or output port with a 3-bit control port

BASIC OPERATION



INPUT OPERATION (READ)					
A_1	A_0	$\overline{RD}$	$\overline{WR}$	$\overline{CS}$	
0	0	0	1	0	PORT A → DATA BUS
0	1	0	1	0	PORT B → DATA BUS
1	0	0	1	0	PORT C → DATA BUS

OUTPUT OPERATION (WRITE)					
A_1	A_0	$\overline{RD}$	$\overline{WR}$	$\overline{CS}$	
0	0	1	0	0	DATA BUS → PORT A
0	1	1	0	0	DATA BUS → PORT B
1	0	1	0	0	DATA BUS → PORT C
1	1	1	0	0	DATA BUS → CONTROL

DISABLE FUNCTION					
A_1	A_0	$\overline{RD}$	$\overline{WR}$	$\overline{CS}$	
X	X	X	X	1	DATA BUS → HIGH Z STATE
X	X	1	1	0	DATA BUS → HIGH Z STATE

NOTES: ① X means "DO NOT CARE."
② All conditions not listed are illegal and should be avoided.

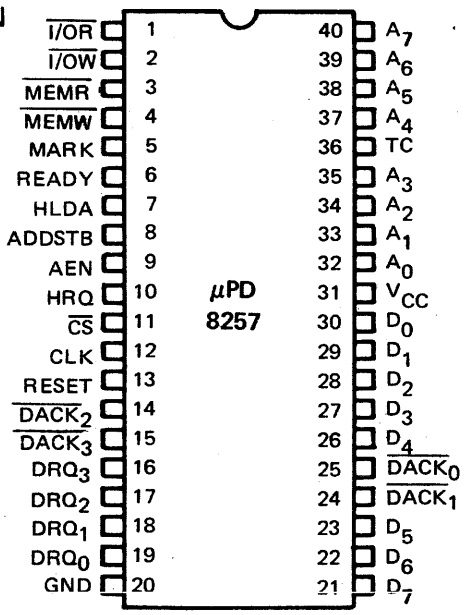
PROGRAMMABLE DMA CONTROLLER



DESCRIPTION

The μPD8257 is a programmable four-channel Direct Memory Access (DMA) controller. It is designed to simplify high speed transfers between peripheral devices and memories. Upon a peripheral request, the 8257 generates a sequential memory address, thus allowing the peripheral to read or write data directly to or from memory. Peripheral requests are prioritized within the 8257 so that the system bus may be acquired by the generation of a single HOLD command to the 8080. DMA cycle counts are maintained for each of the four channels, and a control signal notifies the peripheral when the preprogrammed member of DMA cycles has occurred. Output control signals are also provided which allow simplified sectored data transfers and expansion to other 8257 devices for systems requiring more than four DMA channels.

FEATURES

- Four Channel DMA Controller
- Priority DMA Request Logic
- Channel Inhibit Logic
- Terminal Count and Modulo 128 Outputs
- Automatic Load Mode
- Single TTL Clock
- Single +5V Supply
- Expandable
- 40 Pin Plastic Dual-In-Line Package

μPD8257

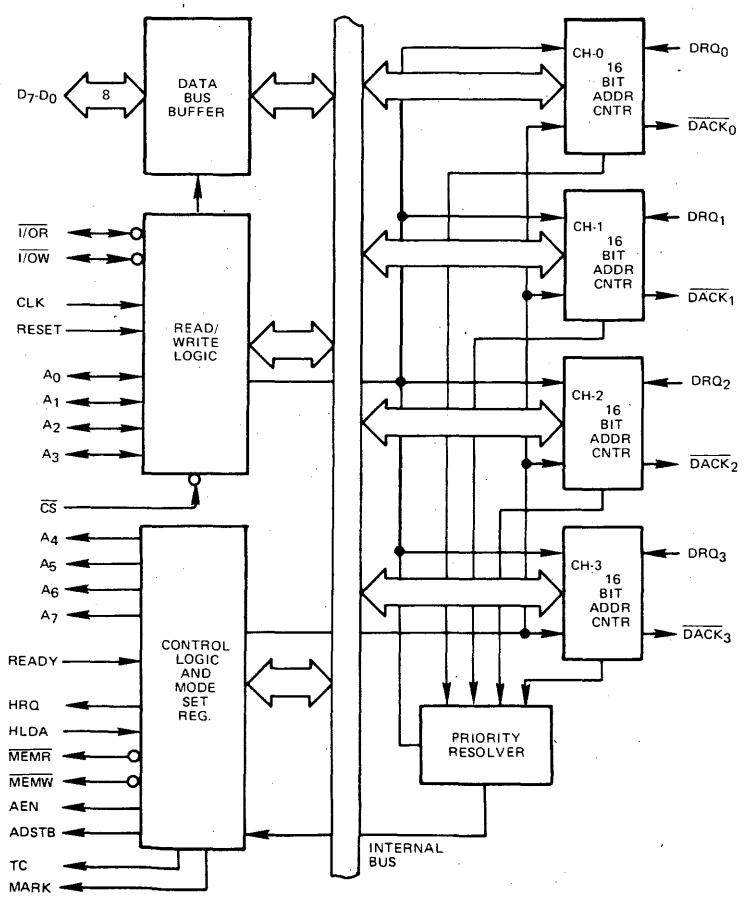
FUNCTIONAL DESCRIPTION

The 8257 is a programmable, Direct Memory Access (DMA) device and when used with an 8212 I/O port device, it provides a complete four-channel DMA controller for use in 8080 based systems. Once initialized by an 8080 CPU, the 8257 will block transfer up to 16,364 bytes of data between memory and a peripheral device without any attention from the CPU, and it will do this on all 4-DMA channels. After receiving a DMA transfer request from a peripheral, the following sequence of events occur within the 8257.

- It acquires control of the system bus (placing 8080 in hold mode).
- Resolves priority conflicts if multiple DMA requests are made.
- A 16 bit memory address word is generated with the aid of an 8212 in the following manner:

  The 8257 outputs the least significant eight bits (A_0-A_7) which go directly onto the address bus.

  The 8257 outputs the most significant eight bits (A_8-A_{15}) onto the data bus where they are latched into an 8212 and then sent to the high order bits on the address bus.
- The appropriate memory and I/O read/write control signals are generated allowing the peripheral to receive or deposit a data byte directly from or to the appropriate memory location.



Block transfer of data (e.g., a sector of data on a floppy disk) either to or from a peripheral may be accomplished as long as the peripheral maintains its DMA Request (DRQ_n). The 8257 retains control of the system bus as long as DRQ_n remains high or until the Terminal Count (TC) is reached. When the Terminal Count occurs, TC goes high, informing the CPU that the operation is complete.

There are three different modes of operation:

- DMA read; which causes data to be transferred from memory to a peripheral;
- DMA write; which causes data to be transferred from a peripheral to memory; and
- DMA verify; which does not actually involve the transfer of data.

The DMA read and write modes are the normal operating conditions for the 8257. The DMA verify mode responds in the same manner as read/write except no memory or I/O read/write control signals are generated, thus preventing the transfer of data. The peripheral gains control of the system bus and obtains DMA Acknowledgements for its requests, thus allowing it to access each byte of a data block for check purposes or accumulation of a CRC (Cyclic Redundancy Code) checkword. In some applications it is necessary for a block of DMA read or write cycles to be followed by a block of DMA verify cycles to allow the peripheral to verify its newly acquired data.

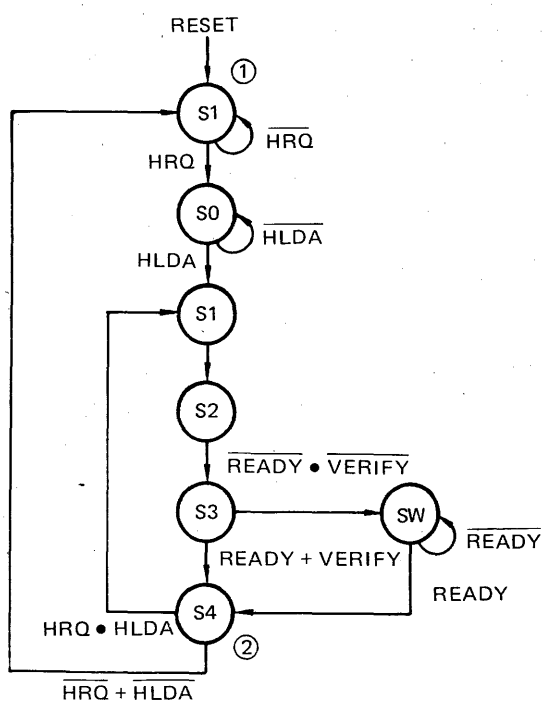
DMA OPERATION

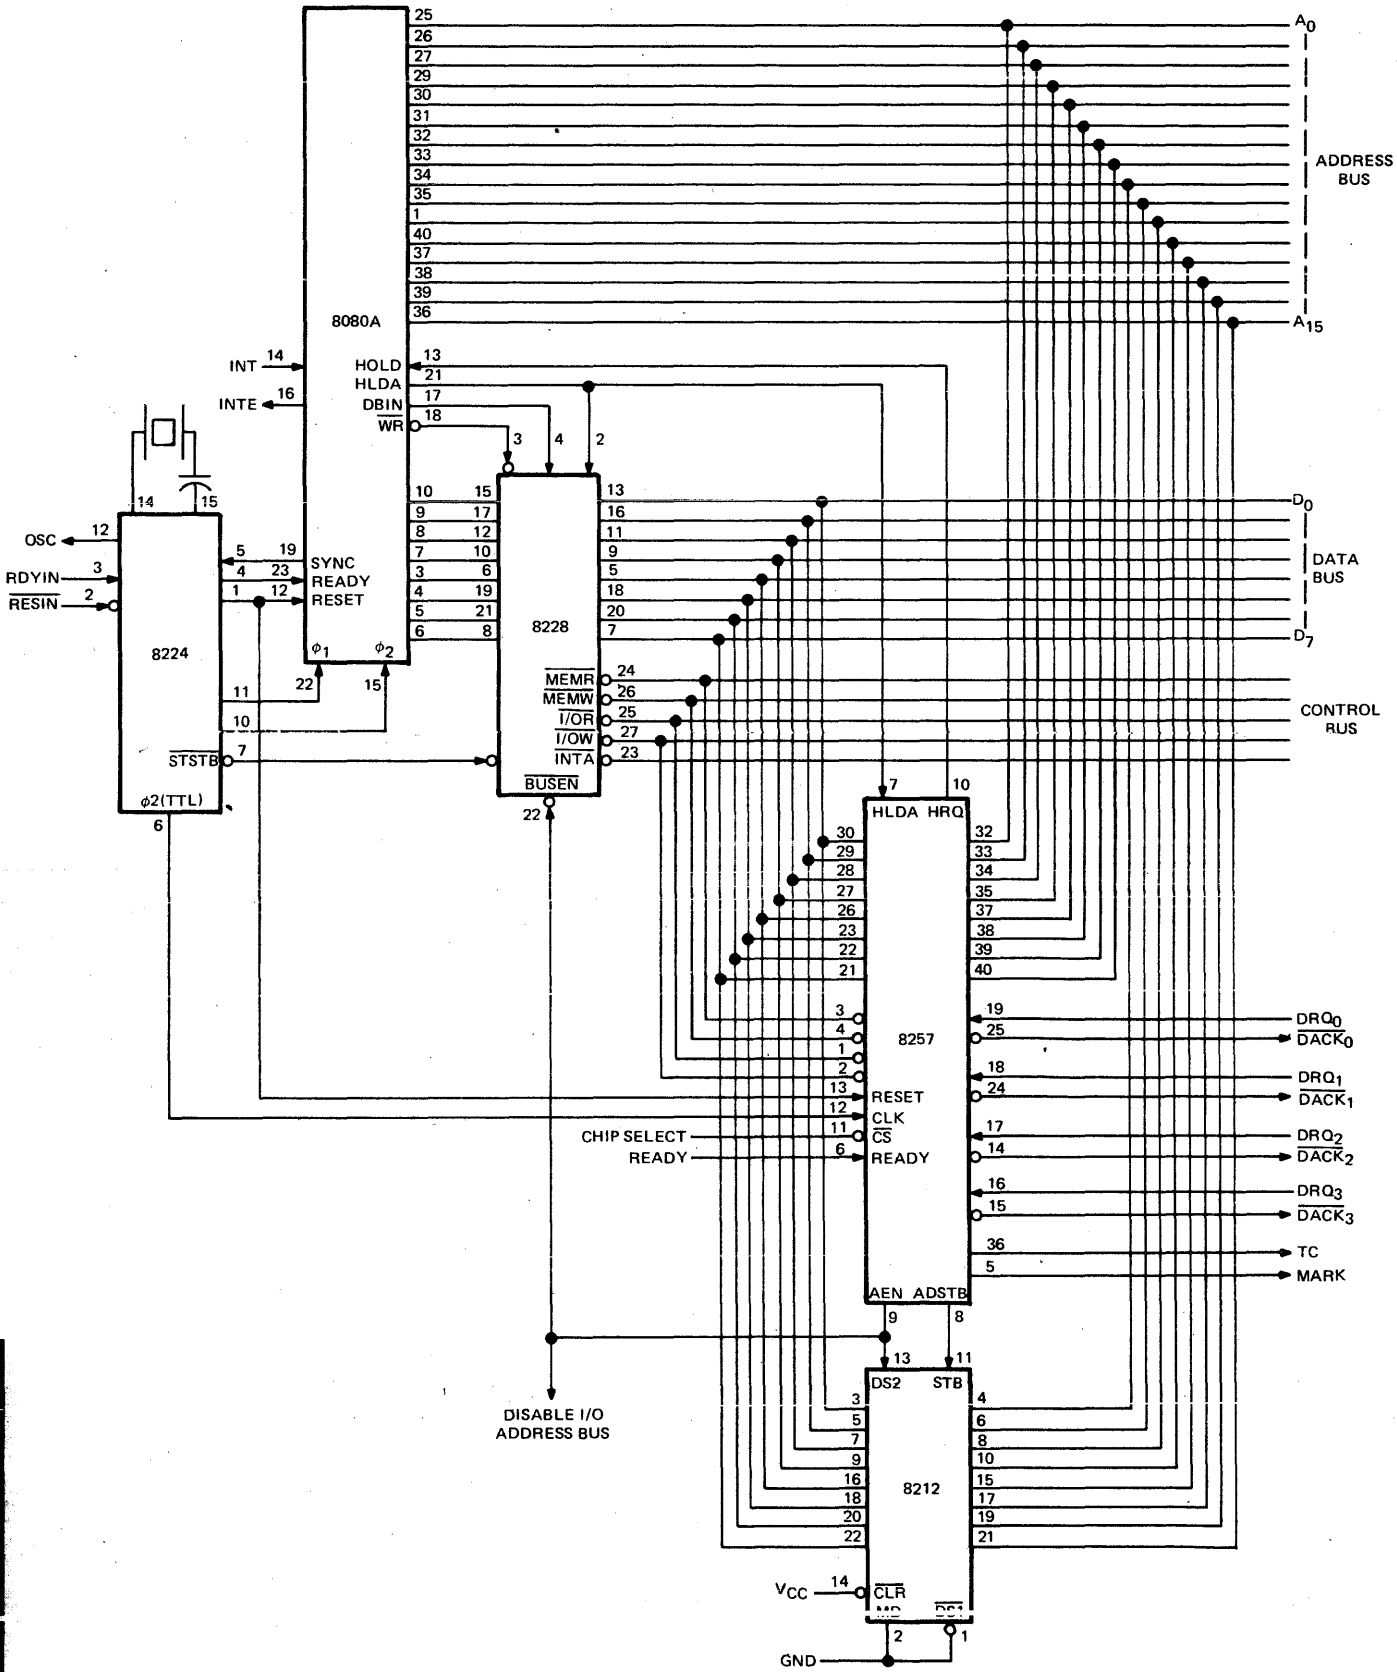


Internally the 8257 contains six different states (S0, S1, S2, S3, S4 and SW), the duration of each state is determined by the input clock. In the idle state, (S1), no DMA operation is being executed. A DMA cycle is started upon receipt of one or more DMA Requests (DRQ_n), then the 8257 enters the S0 state. During state S0 a Hold Request (HRQ) is sent to the 8080 and the 8257 waits in S0 until the 8080 issues a Hold Acknowledge (HLDA) back. During S0, DMA Requests are sampled and DMA priority is resolved (based upon either the fixed or priority scheme). After receipt of HLDA, the DMA Acknowledge line ($\overline{DACK_n}$) with the highest priority is driven low selecting that particular peripheral for the DMA cycle. The DMA Request line (DRQ_n) must remain high until either a DMA Acknowledge ($\overline{DACK_n}$) or both $\overline{DACK_n}$ and TC (Terminal Count) occur, indicating the end of a block or sector transfer (burst mode).

The DMA cycle consists of four internal states; S1, S2, S3 and S4. If the access time of the memory or I/O device is not fast enough to return a Ready command to the 8257 after it reaches state S3, then a Wait state is initiated (SW). One or more than one Wait state occurs until a Ready signal is received, and the 8257 is allowed to go into state S4. Either the extended write option or the DMA Verify mode may eliminate any Wait state.

If the 8257 should lose control of the system bus (i.e., HLDA goes low) then the current DMA cycle is completed, the device goes into the S1 state, and no more DMA cycles occur until the bus is reacquired. Ready setup time (t_{RS}), write setup time (t_{DW}), read data access time (t_{RD}) and HLDA setup time (t_{QS}) should all be carefully observed during the handshaking mode between the 8257 and the 8080.

During DMA write cycles, the I/O Read ($\overline{I/O\ R}$) output is generated at the beginning of state S2 and the Memory Write ($\overline{MEMW}$) output is generated at the beginning of S3. During DMA read cycles, the Memory Read ($\overline{MEMR}$) output is generated at the beginning of state S2 and the I/O Write ($\overline{I/O\ W}$) goes low at the beginning of state S3. No Read or Write control signals are generated during DMA verify cycles.



DMA OPERATION STATE DIAGRAM

Notes: ① HRQ is set if DRQ_n is active.
② HRQ is reset if DRQ_n is not active.

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature	-65°C to +150°C
Voltage on Any Pin	-0.5 to +7 Volts ①
Power Dissipation	1 Watt

Note: ① With Respect to Ground

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

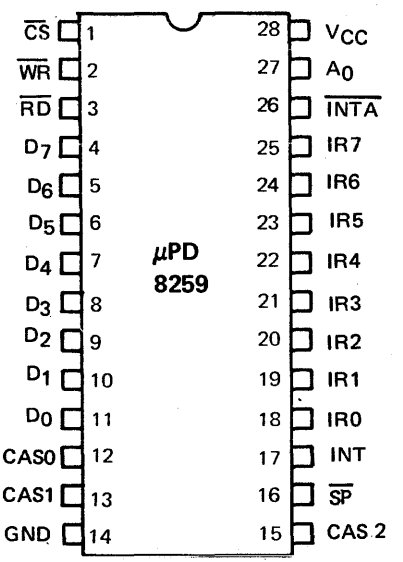
PROGRAMMABLE INTERRUPT CONTROLLER



DESCRIPTION

The NEC μPD8259 is a programmable interrupt controller directly compatible with the 8080A/8085A/μPD780(Z80™). It can service eight levels of interrupts and contains on-chip logic to expand interrupt capabilities up to sixty-four levels with the addition of other μPD8259's. The user is offered a selection of priority algorithms to tailor the priority processing to meet his systems requirements. These algorithms can be dynamically modified during operation, expanding the versatility of the microprocessor system.

FEATURES

- Eight Level Priority Controller
- Programmable Base Vector Address
- Expandable to 64 Levels
- Programmable Interrupt Modes (Algorithms)
- Individual Request Mask Capability
- Single +5V Supply (No Clocks)
- Full Compatibility with 8080A/μPD780(Z80™)
- μPD8259-5 Compatible with 8085A Speeds
- Available in 28 Pin Plastic and Ceramic Packages

PIN CONFIGURATION

PIN NAMES

$D_7 - D_0$	Data Bus (Bi-Directional)
$\overline{RD}$	Read Input
$\overline{WR}$	Write Input
A_0	Command Select Address
CAS2 – CAS0	Cascade Lines
$\overline{SP}$	Slave Program Input
INT	Interrupt Output
$\overline{INTA}$	Interrupt Acknowledge Input
IR0 – iR7	Interrupt Request Inputs
$\overline{CS}$	Chip Select

*All data pertaining to the μPD8259-5 is preliminary.

TM: Z80 is a registered trademark of Zilog, Inc.

INTERRUPT REQUEST REGISTER (IRR) AND IN-SERVICE REGISTER (ISR)

The interrupt request register and in-service register store the in-coming interrupt request signals appearing on the IR0-7 lines (refer to functional block diagram). The inputs requesting service are stored in the IRR while the interrupts actually being serviced are stored in the ISR.

A positive transition on an IR input sets the corresponding bit in the Interrupt Request Register, and at the same time the INT output of the μPD8259 is set high. The IR input line must remain high until the first $\overline{\text{INTA}}$ input has been received. Multiple, non-masked interrupts occurring simultaneously can be stored in the IRR. The incoming $\overline{\text{INTA}}$ sets the appropriate ISR bit (determined by the programmed interrupt algorithm) and resets the corresponding IRR bit. The ISR bit stays high-active during the interrupt service subroutine until it is reset by the programmed End-of-Interrupt (EOI) command.

PRIORITY RESOLVER

The priority resolver decides the priority of the interrupt levels in the IRR. When the highest priority interrupt is determined it is loaded into the appropriate bit of the In-Service register by the first $\overline{\text{INTA}}$ pulse.

DATA BUS BUFFER

The 3-state, 8-bit, bi-directional data bus buffer interfaces the μPD8259 to the processor's system bus. It buffers the Control Word and Status Data transfers between the μPD8259 and the processor bus.

READ/WRITE LOGIC

The read/write logic accepts processor data and stores it in its Initialization Command Word (ICW) and Operation Command Word (OCW) registers. It also controls the transfer of the Status Data to the processor's data bus.

CHIP SELECT ($\overline{\text{CS}}$)

The μPD8259 is enabled when an active-low signal is received at this input. Reading or writing of the μPD8259 is inhibited when it is not selected.

WRITE ($\overline{\text{WR}}$)

This active-low signal instructs the μPD8259 to receive Command Data from the processor.

READ ($\overline{\text{RD}}$)

When an active-low signal is received on the $\overline{\text{RD}}$ input, the status of the Interrupt Request Register, In-Service Register, Interrupt Mask Register or binary code of the Interrupt Level is placed on the data bus.

INTERRUPT (INT)

The interrupt output from the μPD8259 is directly connected to the processor's INT input. The voltage levels of this output are compatible with the 8080's input voltage and timing requirements.

INTERRUPT MASK REGISTER (IMR)

The interrupt mask register stores the bits for the individual interrupt bits to be masked. The IMR masks the data in the ISR. Lower priority lines are not affected by masking a higher priority line.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION (CONT.)

INTERRUPT ACKNOWLEDGE ($\overline{INTA}$)

The interrupt acknowledge signal is usually received from the 8228 (system controller for the 8080A). The system controller generates three $\overline{INTA}$ pulses to signal the 8259 to issue a 3-byte CALL instruction onto the data bus.

A_0

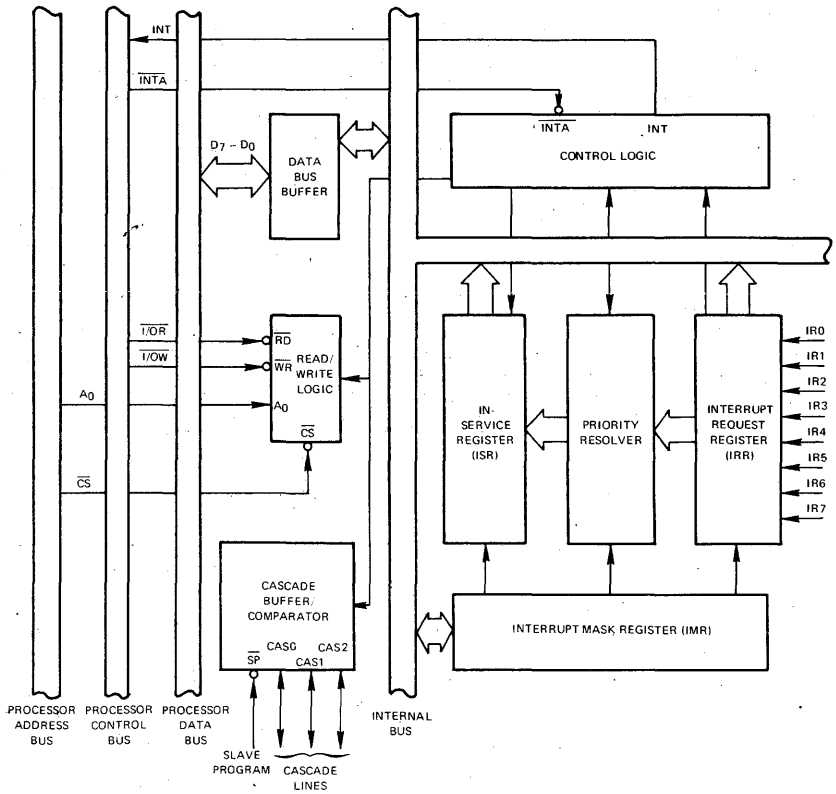
A_0 is usually connected to the processor's address bus. Together with $\overline{WR}$ and $\overline{RD}$ signals it directs the loading of data into the command register or the reading of status data. The following table illustrates the basic operations performed. Note that it is divided into three functions: Input, Output and Bus Disable distinguished by the $\overline{RD}$, $\overline{WR}$, and $\overline{CS}$ inputs.

μPD8259 BASIC OPERATION						
A_0	D_4	D_3	$\overline{RD}$	$\overline{WR}$	$\overline{CS}$	PROCESSOR INPUT OPERATION (READ)
0			0	1	0	IRR, ISR or IR → Data Bus ①
1			0	1	0	IMR → Data Bus
						PROCESSOR OUTPUT OPERATION (WRITE)
0	0	0	1	0	0	Data Bus → OCW2
0	0	1	1	0	0	Data Bus → OCW3
0	1	X	1	0	0	Data Bus → ICW1
1	X	X	1	0	0	Data Bus → OCW1, ICW2, ICW3 ②
						DISABLE FUNCTION
X	X	X	1	1	0	Data Bus → 3-State
X	X	X	X	X	1	Data Bus → 3-State

Notes: ① The contents of OCW2 written prior to the READ operation governs the selection of the IRR, ISR or Interrupt Level.

② The sequencer logic on the μPD8259 aligns these commands in the proper order.

CASCADE BUFFER/COMPARATOR. (For Use in Multiple μPD8259 Array.)



The ID's of all μPD8259's are buffered and compared in the cascade buffer/ comparator. The master μPD8259 will send the ID of the interrupting slave device along the CAS0, 1, 2 lines to all slave devices. The cascade buffer/comparator compares its preprogrammed ID to the CAS0, 1, 2 lines. The next two $\overline{INTA}$ pulses strobe the preprogrammed, 2 byte CALL routine address onto the data bus from the slave whose ID matches the code on the CAS0, 1, 2 lines.

SLAVE PROGRAM ($\overline{SP}$). (For Use in Multiple μPD8259 Array.)

The interrupt capability can be expanded to 64 levels by cascading multiple μPD8259's in a master-plus-slaves array. The master controls the slaves through the $\overline{CAS0}$, 1, 2 lines. The $\overline{SP}$ input to the device selects the CAS0-2 lines as either outputs ($\overline{SP}$=1) for the master or as inputs ($\overline{SP}$=0) for the slaves. For one device only the $\overline{SP}$ must be set to a logic "1" since it is functioning as a master.

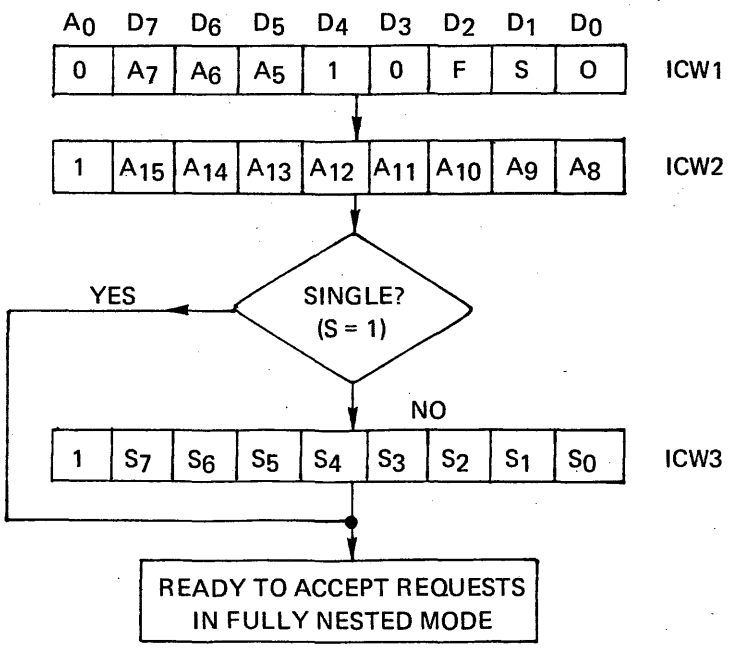
DETAILED OPERATIONAL DESCRIPTION

The μPD8259 derives its versatility from its programmable interrupt modes and its ability to jump to any memory address through programmable CALL instructions. The following sequence demonstrates how the μPD8259 interacts with the processor.



1. An interrupt or interrupts appearing on IR_{0-7} sets the corresponding IR bit(s) high. This in turn sets the corresponding IRR bit(s) high.
2. Once the IRR bit(s) has been set, the μPD8259 will resolve the priorities according to the preprogrammed interrupt algorithm. It then issues an INT signal to the processor.
3. The processor group issues an $\overline{INTA}$ to the μPD8259 when it receives the INT.
4. The $\overline{INTA}$ input to the μPD8259 from the processor group sets the highest priority ISR bit and resets the corresponding IRR bit. The $\overline{INTA}$ also signals the μPD8259 to issue an 8-bit CALL instruction op-code (11001101) onto its Data bus lines.
5. The CALL instruction code instructs the processor group to issue two more $\overline{INTA}$ pulses to the μPD8259.
6. The two $\overline{INTA}$ pulses signal the μPD8259 to place its preprogrammed interrupt vector address onto the Data bus. The first $\overline{INTA}$ releases the low-order 8-bits of the address and the second $\overline{INTA}$ releases the high-order 8-bits.
7. The μPD8259's CALL instruction sequence is complete. A preprogrammed EOI (End-of-Interrupt) command is issued to the μPD8259 at the end of an interrupt service routine to reset the ISR bit and allow the μPD8259 to service the next interrupt.

PROGRAMMING THE μPD8259

Two types of command words are required from the processor to fully define the operating modes of the μPD8259.

1. **Initialization Command Words (ICWs)**

   Each μPD8259 in the interrupt array must be initialized prior to normal operation. The initialization is performed by a 2 or 3-byte sequence clocked by $\overline{WR}$ pulses. Figure 1 shows this sequence. (Refer to Figure 2 for bit definitions.)

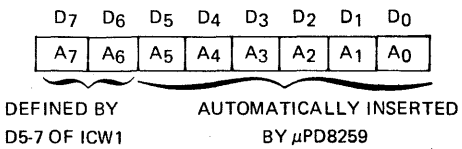
INITIALIZATION SEQUENCE – FIGURE 1.

PROGRAMMING THE μPD8259 (CONT.)

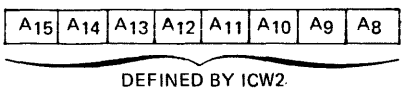
2. Operation Command Words (OCWs)

The operation command words are used to program the various interrupt algorithms listed below:

- Fully Nested Mode
- Rotating Priority Mode
- Special Mask Mode
- Polled Mode



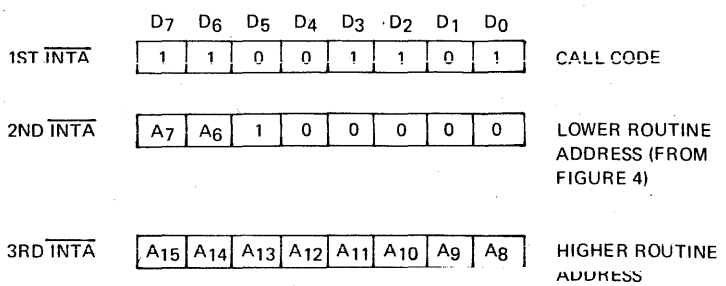
Once the μPD8259 has been initialized, OCWs can be written at any time.



INITIALIZATION COMMAND WORDS 1 and 2 (ICW1 and ICW2)

When $A_0 = 0$ and $D_4 = 1$ in a command to the μPD8259, together with $\overline{CS} = 0$, it is recognized as Initialization Command Word 1. This is the start of the initialization sequence and causes the following to occur:

- The Interrupt Request edge-sense circuitry is reset so that an input must make a low-to-high transition to generate its interrupt.
- The initialization sequence clears Interrupt Mask Register to all unmasked and resets the Special Mask Mode and Status Read Flip-Flops.
- IR_7 input is set to priority 7.



There are eight equally-spaced base vector addresses in memory for the eight interrupt inputs. The interval between the base vector addresses can be programmed to be either four or eight requiring 32 or 64 bytes in memory, respectively. The following shows how the address format is mapped onto the Data bus.

The μPD8259 automatically defines A_{0-4} with a separate address for each interrupt input. The base vector addresses A_{15-6} are programmed by ICW1 and ICW2. A_5 is either defined by the μPD8259 if the address interval is eight or must be user-defined if the interval is 4. The 8-byte CALL interval is consistent with 8080A processor RESTART instruction software. The 4-byte CALL interval can be used for a compact jump table. Refer to Figure 4 for a table of address formats.

The following is an example of an interrupt acknowledge sequence. The μPD8259 has been programmed for a CALL address (base vector address) interval of eight (F = 0) and there is an interrupt appearing on IR_4. The 3-byte sequence is strobed out to the Data bus by three $\overline{INTA}$ pulses.

©IC MASTER 1979

INITIALIZATION COMMAND WORD 3 (ICW3) ①

It is only necessary to program ICW3 when there are multiple μPD8259s in the interrupt array, i.e., S = 0. There are two types of ICW3s. The first is for programming the master μPD8259. The second is for the slaves.

1. ICW3-Master μPD8259. A "1" is set in S_{0-7} for each corresponding slave in the interrupt array. The S_{0-7} bits, together with $\overline{SP}$ = 1, instructs the cascade buffer/comparator to send the ID of the interrupting slave on the CAS0,1,2 lines.
2. ICW3-SLAVE μPD8259(s). Bits D_7-D_3 are "don't care" bits and have no effect on ICW3. The ID of each slave is programmed by bits D_{0-2} ($ID_{0,1,2}$). Once the master μPD8259 has sent out the first byte of the CALL sequence, the slave device(s) with their $\overline{SP}$ inputs set to Logic 0, compare their IDs appearing on the CAS0,1,2 lines through the cascade buffer/comparator. The slave whose ID matches the CAS0,1,2 code then issues bytes 2 and 3 of the CALL sequence.

OPERATIONAL COMMAND WORDS (OCWs) ②

Once the μPD8259 has been programmed with Initialization Command Words, it can now be programmed for the appropriate interrupt algorithm by the Operation Command Words. Interrupt algorithms in the μPD8259 can be changed at any time during program operation by issuing another set of Operation Command Words. The following sections describe the various algorithms available and their associated OCWs.

INTERRUPT MASKS

The individual Interrupt Request input lines are maskable by setting the corresponding bits in the Interrupt Mask Register to a logic "1" through OCW1. The actual masking is performed upon the contents of the In-Service Register (e.g., if Interrupt Request line 3 is to be masked, then only bit 3 of the IMR is set to logic "1." The IMR in turn acts upon the contents of the ISR to mask bit 3). Once the μPD8259 has acknowledged an interrupt, i.e., the μPD8259 has sent an INT signal to the processor and the system controller has sent it an $\overline{INTA}$ signal, the interrupt input, although it is masked, will inhibit lower priority requests from being acknowledged. There are two means of enabling these lower priority interrupt lines. The first is by issuing an End-of-Interrupt (EOI) through Operation Command Word 2 (OCW2), thereby resetting the appropriate ISR bit. The second approach is to select the Special Mask Mode through OCW3. The Special Mask Mode (SMM) and End-of-Interrupt (EOI) will be described in more detail further on.

FULLY NESTED MODE

The fully nested mode is the μPD8259's basic operating mode. It will operate in this mode after the initialization sequence, requiring no Operation Command Words for formatting. Priorities are set IR_0 through IR_7 with IR_0 the highest priority. After the interrupt has been acknowledged by the processor and system controller, only higher priorities will be serviced. Upon receiving an $\overline{INTA}$, the priority resolver determines the priority of the interrupt, the corresponding ISR bit is set, and the vector address is output to the Data bus. The EOI command resets the corresponding ISR bit at the end of its service routine.

Notes: ① Reference Figure 2
② Reference Figure 3

©IC MASTER 1979

OPERATIONAL COMMAND WORDS (CONT.)

ROTATING PRIORITY MODE COMMANDS

The two variations of Rotating Priorities are the Auto Rotate and Specific Rotate modes. These two modes are typically used to service interrupting devices of equivalent priorities.

1. Auto Rotate Mode

   Programming the Auto Rotate Mode through OCW2 assigns priorities 0-7 to the interrupt request input lines. Interrupt line IR_0 is set to the highest priority and IR_7 to the lowest. Once an interrupt has been serviced it is automatically assigned the lowest priority. That same input must then wait for the devices ahead of it to be serviced before it can be acknowledged again. The Auto Rotate Mode is selected by programming OCW2 in the following way (refer to Figure 3): set Rotate Priority bit "R" to a logic "1"; program EOI to a logic "1" and SEOI to a logic "0." The EOI and SEOI commands are discussed further on. The following is an example of the Auto Rotate Mode with devices requesting interrupts on lines IR_2 and IR_5.

   Before Interrupts are Serviced:

	IS_7	IS_6	IS_5	IS_4	IS_3	IS_2	IS_1	IS_0
In-Service Register	0	0	1	0	0	1	0	0
						→		Highest Priority
Priority Status Register	IR_7	IR_6	IR_5	IR_4	IR_3	IR_2	IR_1	IR_0

   According to the Priority Status Register, IR_2 has a higher priority than IR_5 and will be serviced first.

   After Servicing:

	IS_7	IS_6	IS_5	IS_4	IS_3	IS_2	IS_1	IS_0
In-Service Register	0	0	1	0	0	0	0	0
						→		Highest Priority
Priority Status Register	IR_2	IR_1	IR_0	IR_7	IR_6	IR_5	IR_4	IR_3

   At the completion of IR_2's service routine the corresponding In-Service Register bit, IS_2 is reset to "0" by the preprogrammed EOI command. IR_2 is then assigned the lowest priority level in the Priority Status Register. The μPD8259 is now ready to service the next highest interrupt, which in this case, is IR_5.

2. Specific Rotate Mode

   The priorities are set by programming the lowest level through OCW2. The μPD8259 then automatically assigns the highest priority. If, for example, IR_3 is set to the lowest priority (bits L_2, L_1, L_0 form the binary code of the bottom priority level), then IR_4 will be set to the highest priority. The Specific Rotate Mode is selected by programming OCW2 in the following manner: set Rotate Priority bit "R" to a logic "1," program EOI to a logic "0," SEOI to a logic "1" and L_2, L_1, L_0 to the lowest priority level. If EOI is set to a logic "1," the ISR bit defined by L_2, L_1, L_0 is reset.

©IC MASTER 1979

END-OF-INTERRUPT (EOI) AND SPECIFIC END-OF-INTERRUPT (SEOI)

The End-of-Interrupt or Specific End-of-Interrupt command must be issued to reset the appropriate In-Service Register bit before the completion of a service routine. Once the ISR bit has been reset to logic "0," the μPD8259 is ready to service the next interrupt.

Two types of EOIs are available to clear the appropriate ISR bit depending on the μPD8259's operating mode.

1. Non-Specific End-of-Interrupt (EOI)

   When operating in interrupt modes where the priority order of the interrupt inputs is preserved (e.g., fully nested mode), the particular ISR bit to be reset at the completion of the service routine can be determined. A non-specific EOI command will automatically reset the highest priority ISR bit of those set. The highest priority ISR bit must necessarily be the interrupt being serviced and must necessarily be the service subroutine returned from.

2. Specific End-of-Interrupt (SEOI)

   When operating in interrupt modes where the priority order of the interrupt inputs is not preserved (e.g., rotating priority mode) the last serviced interrupt level may not be known. In these modes a Specific End-of-Interrupt must be issued to clear the ISR bit at the completion of the interrupt service routine. The SEOI is programmed by setting the appropriate bits in OCW3 (Figure 2) to logic "1"s. Both the EOI and SEOI bits of OCW3 must be set to a logic "1" with L_2, L_1, L_0 forming the binary code of the ISR bit to be reset.

SPECIAL MASK MODE

Setting up an interrupt mask through the Interrupt Mask Register (refer to Interrupt Mask Register section) by setting the appropriate bits in OCW1 to a logic "1" will inhibit lower priority interrupts from being acknowledged. In applications requiring that the lower priorities be enabled while the IMR is set, the Special Mask Mode can be used. The SMM is programmed in OCW3 by setting the appropriate bits to a logic "1." Once the SMM is set, the μPD8259 remains in this mode until it is reset. The Special Mask Mode does not affect the higher priority interrupts.

POLLED MODE

In the Poll Mode the processor must be instructed to disable its interrupt input (INT). Interrupt service is initiated through software by a Poll Command. The Poll Mode is programmed by setting the Poll Mode bit in OCW3 (P = 1), during a $\overline{WR}$ pulse. The following $\overline{RD}$ pulse is then considered as an interrupt acknowledge. If an interrupt input is present, that $\overline{RD}$ pulse sets the appropriate ISR bit and reads the interrupt priority level. The Poll Mode is a one-time operation and must be programmed through OCW3 before every read. The word strobed onto the Data bus during Poll Mode is of the form:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
I	X	X	X	X	W_2	W_1	W_0

where: I = 1 if there is an interrupt requesting service
= 0 if there are no interrupts

$W_{2\text{-}0}$ forms the binary code of the highest priority level of the interrupts requesting service

The Poll Mode can be used when an interrupt service routine is common to several interrupt inputs. The $\overline{INTA}$ sequence is no longer required offering a saving in ROM space. The Poll Mode can also be used to expand the number of interrupts beyond 64.

©IC MASTER 1979

READING μPD8259 STATUS

The following major registers' status is available to the processor by appropriately formatting OCW3 and issuing a $\overline{RD}$ command.

INTERRUPT REQUEST REGISTER (8-BITS)

The Interrupt Request Register stores the interrupt levels awaiting acknowledgement. Once it has been acknowledged, the highest priority in-service bit is reset. (Note that the Interrupt Mask Register has no effect on the IRR.) A $\overline{WR}$ command must be issued with OCW3 prior to issuing the $\overline{RD}$ command. The bits which determine whether the IRR and ISR are being read from are RIS and ERIS. To read contents of the IRR, ERIS must be logic "1" and RIS a logic "0."

IN-SERVICE REGISTER (8-BITS)

The In-Service Register stores the priorities of the interrupt levels being serviced. Assertion of an End-of-Interrupt (EOI) updates the ISR to the next priority level. A $\overline{WR}$ command must be issued with OCW3 prior to issuing the $\overline{RD}$ command. Both ERIS and RIS should be set to a logic "1."

INTERRUPT MASK REGISTER (8-BITS)

The Interrupt Mask Register holds mask data modifying interrupt levels. To read the IMR status a $\overline{WR}$ pulse preceding the $\overline{RD}$ is not necessary. The IMR data is available to the data bus when $\overline{RD}$ is asserted with A_0 at a logic "1."

A single OCW3 is sufficient to enable successive status reads providing it is of the same register. A status read is over-ridden by the Poll Mode where bits P and ERIS of OCW3 are set to a logic "1."

CASCADING MULTIPLE μPD8259s

If more than eight interrupt levels are required, multiple μPD8259s can be cascaded with one master and up to eight slaves, to accommodate up to 64 levels of interrupt.

As shown in Figure 5, the master device directs the appropriate slave to release its CALL address through its three cascade lines (CAS0,1,2).

The INT output of the slave devices go to the IR inputs of the master device. The master μPD8259's INT output is connected to the processor's control bus. When the slave device signals the master that it has acknowledged an interrupt, the master issues an 8080A CALL Op-code at the first $\overline{INTA}$ pulse. The master then signals that slave device (via CAS0,1,2) to issue the appropriate CALL address during the second and third $\overline{INTA}$ pulses.

The slave address code is present on cascade lines 0,1,2 (active-high logic) from the trailing edge of the first $\overline{INTA}$ to the trailing edge of the third $\overline{INTA}$. Each device in the μPD8259 array must be individually initialized and can be programmed in different operating modes. Two End-of-Interrupt commands must be issued for the master and its corresponding slave. An address decoder is used to drive the Chip Select inputs for each μPD8259 in the array. The Slave Program ($\overline{SP}$) input must be held at a logic "0" level for each slave device and held at logic "1" level for the master. The $\overline{SP}$ input selects the Cascade lines as either inputs ($\overline{SP}$ = 0) or outputs ($\overline{SP}$ = 1).

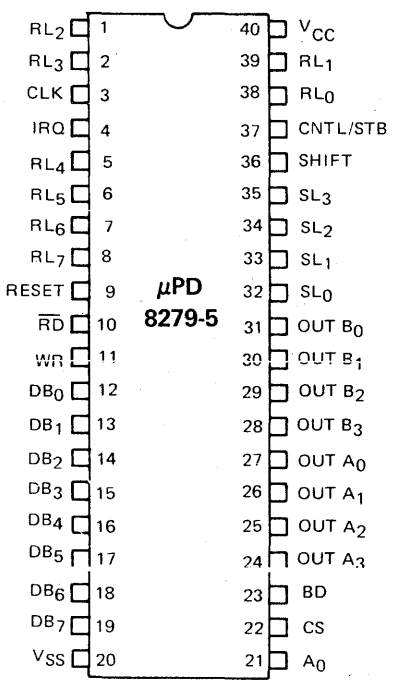
PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

DESCRIPTION



The μPD8279-5 is a programmable keyboard and display Input/Output device. It provides the user with the ability to display data on alphanumeric segment displays or simple indicators. The display RAM can be programmed as 16 x 8 or a dual 16 x 4 and loaded or read by the host processor. The display can be loaded with right or left entry with an auto-increment of the display RAM address.

The keyboard interface provides a scanned signal to a 64 contact key matrix expandable to 128. General sensors or strobed keys may also be used. Keystrokes are stored in an 8 character FIFO and can be either 2 key lockout or N key rollover. Keyboard entries generate an interrupt to the processor.

FEATURES

- Programmable by Processor
- 32 HEX or 16 Alphanumeric Displays
- 64 Expandable to 128 Keyboard
- Simultaneous Keyboard and Display
- 8 Character Keyboard – FIFO
- 2 Key Lockout or N Key Rollover
- Contact Debounce
- Programmable Scan Timer
- Interrupt on Key Entry
- Single +5 Volt Supply
- Fully Compatible with 8080A, 8085A, μPD780 (Z80™)
- Available in 40 Pin Plastic Package

PIN CONFIGURATION

PIN NAMES

DB_{0-7}	Data Bus (Bi-directional)
CLK	Clock Input
RESET	Reset Input
$\overline{CS}$	Chip Select
$\overline{RD}$	Read Input
$\overline{WR}$	Write Input
A_0	Buffer Address
IRQ	Interrupt Request Output
SL_{0-3}	Scan Lines
RL_{0-7}	Return Lines
SHIFT	Shift Input
CNTL/STB	Control/Strobe Input
$OUT\ A_{0-3}$	Display (A) Outputs
$OUT\ B_{0-3}$	Display (B) Outputs
$\overline{BD}$	Bland Display Output

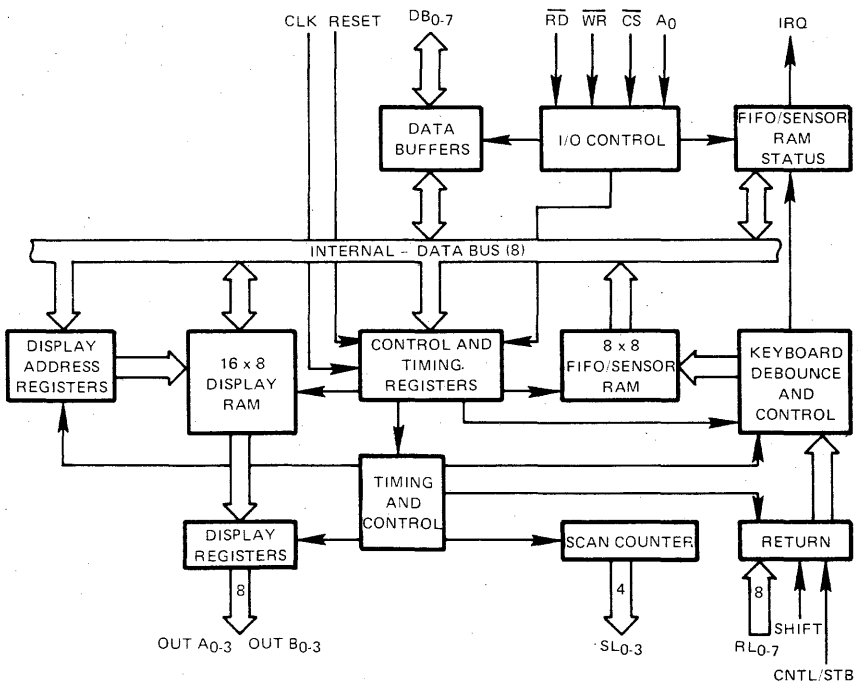
μPD8279-5

FUNCTIONAL DESCRIPTION

The μPD8279-5 has two basic functions: 1) to control displays to output and 2) to control a keyboard for input. Its specific purpose is to unburden the host processor from monitoring keys and refreshing displays. The μPD8279-5 is designed to directly interface the microprocessor bus. The microprocessor must program the operating mode to the μPD8279-5, these modes are as follows:



Output Modes

- 8 or 16 Character Display
- Right or Left Entry

Input Modes

- Scanned Keyboard with Encoded 8 x 8 x 4 Key Format or Decoded 4 x 8 x 8 Scan Lines.
- Scanned Sensor Matrix with Encoded 8 x 8 or Decoded 4 x 8 Scan Lines.
- Strobed Input.

BLOCK DIAGRAM

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature	-65°C to +125°C

PIN IDENTIFICATION

PIN			DESCRIPTION
NO.	SYMBOL	NAME	
1, 2, 5, 6, 7, 8, 38, 39	RL_{0-7}	Return Lines	Return line inputs which are connected to the scan lines through the keys or sensor switches. They have active internal pullups to keep them high until a switch closure pulls one low. They also serve as an 8-bit input in the Strobed Input mode.
3	CLK	Clock	Clock from system used to generate internal timing.
4	IRQ	Interrupt Request	Interrupt Request. In a keyboard mode, the interrupt line is high when there is data in the FIFO/Sensor RAM. The interrupt line goes low with each FIFO/Sensor RAM read and returns high if there is still information in the RAM. In a sensor mode, the interrupt line goes high whenever a change in a sensor is detected.
9	Reset	Reset Input	A high signal on this pin resets the μPD8279-5.
10	$\overline{RD}$	Read Input	Input/Output read and write. These signals enable the data buffers to either send data to the external bus or receive it from the external bus.
11	$\overline{WR}$	Write Input	
12-19	DB_{0-7}	Data Bus	Bi-Directional data bus. All data and commands between the processor and the μPD8279-5 are transmitted on these lines.
20	V_{SS}	Ground Reference	Power Supply Ground
21	A_0	Buffer Address	Buffer Address. A high on this line indicates the signals in or out are interpreted as a command or status. A low indicates that they are data.
22	$\overline{CS}$	Chip Select	Chip Select. A low on this pin enables the interface functions to receive or transmit.
23	$\overline{BD}$	Blank Display Output	Blank Display. This output is used to blank the display during digit switching or by a display blanking command.
24-27	$OUT\ A_{0-3}$	Display A Outputs	These two ports are the outputs for the 16 x 4 display refresh registers. The data from these outputs is synchronized to the scan lines (SL_0-SL_3) for multiplexed digit displays. The two 4-bit ports may be blanked independently. These two ports may also be considered as one 8-bit port.
28-31	$OUT\ B_{0-3}$	Display B Outputs	
32-35	SL_{0-3}	Scan Lines	Scan Lines which are used to scan the key switch or sensor matrix and the display digits. These lines can be either encoded (1 of 16) or decoded (1 of 4).
36	Shift	Shift Input	The shift input status is stored along with the key position on key closure in the Scanned Keyboard modes. It has an active internal pullup to keep it high until a switch closure pulls it low.
37	CNTL/STB	Control/ Strobe Input	For keyboard modes this line is used as a control input and stored like status on a key closure. The line is also the strobe line that enters the data into the FIFO in Strobed input mode (Rising Edge). It has an active internal pullup to keep it high until a switch closure pulls it low.
40	V_{CC}	+5V Input	Power Supply Input

©IC MASTER 1979

OPERATIONAL DESCRIPTION

The following is a description of each section of the μPD8279-5. See the block diagram for functional reference.

I/O Control and Data Buffers

Communication to and from the μPD8279-5 is performed by selecting $\overline{CS}$, A_0, $\overline{RD}$ and $\overline{WR}$. The type of information written or read by the processor is selected by A_0. A logic 0 states that information is data while a 1 selects command or status. $\overline{RD}$ and $\overline{WR}$ select the direction by which the transfer occurs through the Data Buffers. When the chip is deselected ($\overline{CS}$ = 1) the bi-directional Data Buffers are in a high impedance state thus enabling the μPD8279-5 to be tied directly to the processor data bus.

Timing Registers and Timing Control

The Timing Registers store the display and keyboard modes and other conditions programmed by the processor. The timing control contains the timing counter chain. One counter is a divide by N scaler which may be programmed to match the processor cycle time. The scaler must take a value between 2 and 31 in binary. A value which scales the internal frequency to 100 KHz gives a 5.1 ms scan time and 10.3 ms switch debounce. The other counters divide down to make key, row matrix and display scans.

Scan Counter

The scan counter can operate in either the encoded or decoded mode. In the encoded mode, the counter provides a count which must be decoded to provide the scan lines. In the decoded mode, the counter provides a 1 out of 4 decoded scan. In the encoded mode the scan lines are active high and in the decoded mode they are active low.

Return Buffers, Keyboard Debounce and Control

The eight return lines are buffered and latched by the return buffers. In the keyboard mode these lines are scanned sampling for key closures in each row. If the debounce circuit senses a closure, about 10 ms are timed out and a check is performed again. If the switch is still pressed, the address of the switch matrix plus the status of shift and control are written into the FIFO. In the scanned sensor mode, the contents of return lines are sent directly to the sensor RAM (FIFO) each key scan. In the strobed mode, the transfer takes place on the rising edge of CNTL/STB.

FIFO/Sensor RAM and Status

This section is a dual purpose 8 x 8 RAM. In strobe or keyboard mode it is a FIFO. Each entry is pushed into the FIFO and read in order. Status keeps track of the number of entries in the FIFO. Too many reads or writes to the FIFO will be treated as an error condition. The status logic generates an IRQ whenever the FIFO has an entry. In the sensor mode the memory is a sensor RAM which detects changes in the status of a sensor. If a change occurs, the IRQ is generated until the change is acknowledged.

Display Address Registers and Display RAM

The Display Address Register contains the address of the word being read or written by the processor, as well as the word being displayed. This address may be programmed to auto-increment after each read or write. The display RAM may be read by the processor any time after the mode and address is set. Data entry to the display RAM may be set to either right or left entry.

©IC MASTER 1979

COMMAND OPERATION

The commands programmable to the μPD8279-5 via the data bus with $\overline{CS}$ active (0) and A_0 high are as follows:

Keyboard/Display Mode Set

0	0	0	D	D	K	K	K

MSB LSB

Display Mode:

DD

0	0	8-8-bit character display – Left entry
0	1 ①	16-8 bit character display – Left entry
1	0	8-8 bit character display – Right entry
1	1	16-8 bit character display – Right entry

Note: ① Power on default condition

Keyboard Mode:

KKK

0	0	0	Encoded Scan – 2 Key Lockout
0	0	1	Decoded Scan – 2 Key Lockout
0	1	0	Encoded Scan – N Key Rollover
0	1	1	Decoded Scan – N Key Rollover
1	0	0	Encoded Scan-Sensor Matrix
1	0	1	Decoded Scan-Sensor Matrix
1	1	0	Strobed Input, Encoded Display Scan
1	1	1	Strobed Input, Decoded Display Scan

Program Clock

0	0	1	P	P	P	P	P

Where PPPPP is the prescaler value between 2 and 31 this prescaler divides the external clock by PPPPP to develop its internal frequency. After reset, a default value of 31 is generated.

Read FIFO/Sensor RAM

0	1	0	A1	X	A	A	A

$A_0 = 0$

A_I is the auto-increment flag. AAA is the row to be read by the processor. The read command is accomplished with ($\overline{CS} \cdot RD \cdot \overline{A0}$) by the processor. If A_I is 1, the row select counter will be incremented after each read. Note that auto-incrementing has no effect on the display.

Read Display RAM

0	1	1	A1	A	A	A	A

$A_0 = 0$

Where A_I is the auto-increment flag and AAAA is the character which the processor is about to read.

Write Display RAM

1	0	0	A1	A	A	A	A

where AAAA is the character the processor is about to write.

Display Write Inhibit Blanking

1	0	1	X	IW A	IW B	BL A	BL B

Where IWA and IWB are Inhibit Writing nibble A and B respectively, and BLA, BLB are blanking. When using the display as a dual 4-bit, it is necessary to mask one of the 4-bit halves to eliminate interaction between the two halves. This is accomplished with the IW flags. The BL flags allow the programmer to blank either half of the display independently. To blank a display formatted as a single 8-bit, it is necessary to set both BLA and BLB. Default after a reset is all zeros. All signals are active high (1).

©IC MASTER 1979

Clear

1	1	0	C_D	C_D	C_D	C_F	C_A

C_D	C_D	C_D	
1	0	X	All zeros
1	1	0	AB = 20_{16}
1	1	1	All ones
0	X	X	Disable clear display

This command is used to clear the display RAM, the FIFO, or both. The C_D options allow the user the ability to clear the display RAM to either all zeros or all ones.

C_F clears the FIFO.
C_A clears all.

Clearing the display takes one complete display scan. During this time the processor can't write to the display RAM.

C_F will set the FIFO empty flag and reset IRQ. The sensor matrix mode RAM pointer will then be set to row 0.

C_A is equivalent to C_F and C_D. The display is cleared using the display clear code specified and resets the internal timing logic to synchronize it.

End Interrupt/Error Mode Set

1	1	1	E	X	X	X	X

In the sensor matrix mode, this instruction clears IRQ and allows writing into RAM.

In N key rollover, setting the E bit to 1 allows for operating in the special Error mode. See Description of FIFO status.

FIFO Status

D_U	S/E	O	U	F	N	N	N

Where: D_U = Display Unavailable because a clear display or clear all command is in progress.
S/E = Sensor Error flag due to multiple closure of switch matrix.
O = FIFO Overrun since an attempt was made to push too many characters into the FIFO.
U = FIFO Underrun. An indication that the processor tried to read an empty FIFO.
F = FIFO Full Flag.
NNN = The Number of characters presently in the FIFO.

The FIFO Status is Read with A_0 high and $\overline{CS}$, $\overline{RD}$ active low.

The Display not available is an indication that the C_D or C_A command has not completed its clearing. The S/E flags are used to show an error in multiple closures has occurred. The O or U, overrun or underrun, flags occur when too many characters are written into the FIFO or the processor tries to read an empty FIFO. F is an indication that the FIFO is full and NNN is the number of characters in the FIFO.

Data Read

Data can be read during A_0 = 0 and when $\overline{CS}$, $\overline{RD}$ are active low. The source of the data is determined by the Read Display or Read FIFO commands.

Data Write

Data is written to the chip when A_0, $\overline{CS}$, and $\overline{WR}$ are active low. Data will be written into the display RAM with its address selected by the latest Read or Write Display command.

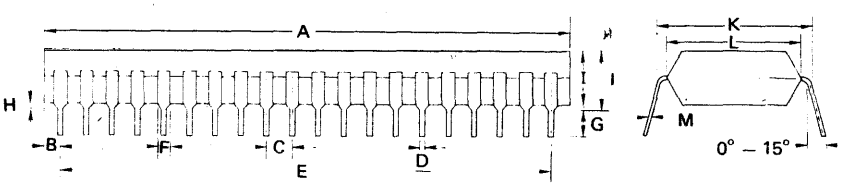
©IC MASTER 1979

COMMAND OPERATION (CONT.)

Data Format

CNTL	SH	SCAN	RET

In the Scanned Key mode, the characters in the FIFO correspond to the above format where CNTL and SH are the most significant bits and the SCAN and return lines are the scan and column counters.



RL_7	RL_6	RL_5	RL_4	RL_3	RL_2	RL_1	RL_0

In the Sensor Matrix mode, the data corresponds directly to the row of the sensor RAM being scanned. Shift and control (SH, CNTL) are not used in this mode.

Control Address Summary

A_0	MSB			DATA				LSB	
1	0	0	0	D	D	K	K	K	Keyboard Display Mode Set

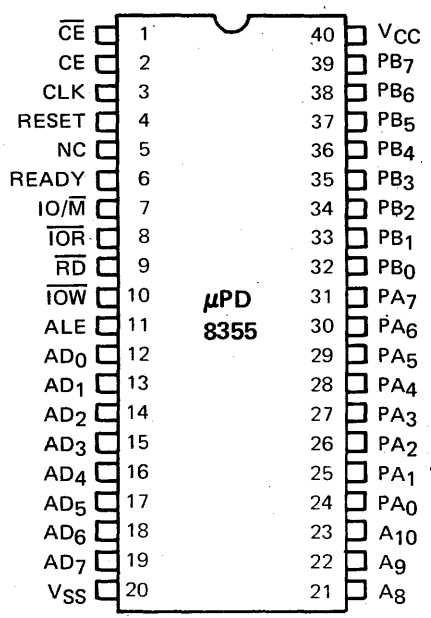
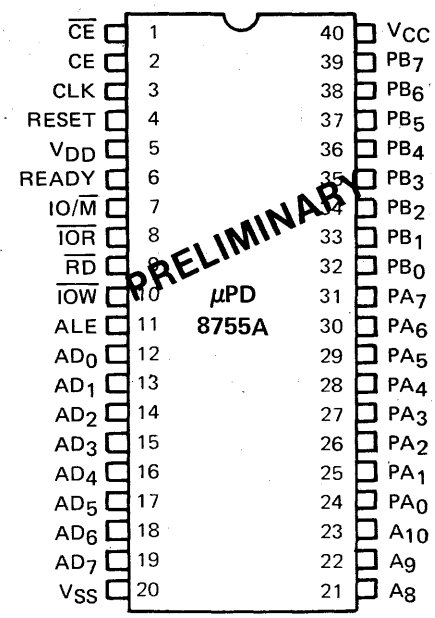
NEC
μPD8355
μPD8755A*

16,384 BIT ROM WITH I/O PORTS
16,384 BIT EPROM WITH I/O PORTS*



DESCRIPTION



The μPD8355 and the μPD8755A are μPD8085A Family components with the μPD8355 containing 2048 X 8 bits of mask ROM and the μPD8755A containing 2048 X 8 bits of mask EPROM for program development. Both components also contain two general purpose 8-bit I/O ports. They are housed in 40 pin packages, are designed to directly interface to the μPD8085A and are pin for pin compatible to each other.

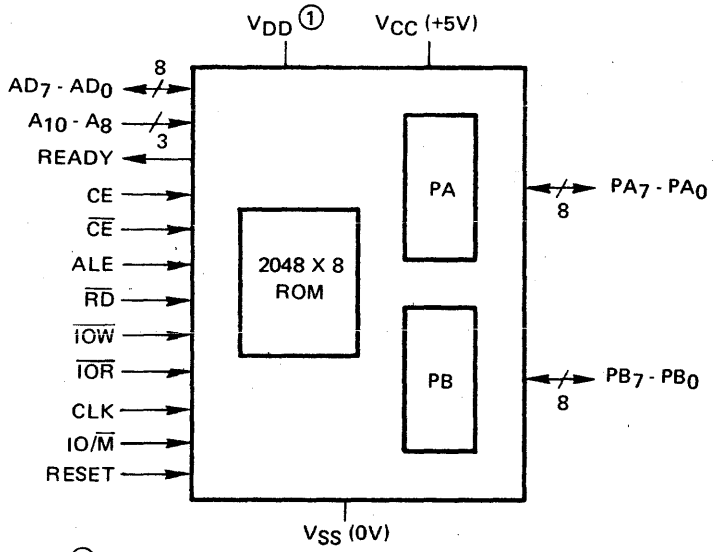
FEATURES

- 2048 X 8 Bits Mask ROM (μPD8355)
- 2048 X 8 Bits Mask EPROM (μPD8755A)
- 2 Programmable I/O Ports
- Single Power Supplies: +5V
- Directly Interfaces to the μPD8085A
- Pin for Pin Compatible
- μPD8755A: UV Eraseable and Electrically Programmable
- μPD8355 available in Plastic Package
- μPD8755A Available in Ceramic Package

PIN CONFIGURATIONS

NC: Not Connected

*All data pertaining to the μPD8755A is preliminary.



©IC MASTER 1979

FUNCTIONAL DESCRIPTION

The μPD8355 and μPD8755A contain 16,384 bits of mask ROM and EPROM respectively, organized as 2048 X 8. The 2048 word memory location may be selected anywhere within the 64K memory space by using the upper 5-bits of address from the μPD8085A as a chip select.

The two general purpose I/O ports may be programmed input or output at any time. Upon power up, they will be reset to the input mode.

② μPD8755A

I/O PORTS

I/O Port activity is controlled by performing I/O reads and writes to selected I/O port numbers. Any activity to and from the μPD8355 requires the chip enables to be active. This can be accomplished with no external decoding for multiple devices by utilizing the upper address lines for chip selects. ① Port activity is controlled by the following I/O addresses:

AD_1	AD_0	PORT SELECTED	FUNCTION
0	0	A	Read or Write PA
0	1	B	Read or Write PB
1	0	A	Write PA Data Direction
1	1	B	Write PB Data Direction

Since the data direction registers for PA and PB are each 8-bits, any pin on PA or PB may be programmed as input or output (0 = in, 1 = out).

Note: ① During ALE time the data/address lines are duplicated on A_{15}-A_8.

EPROM PROGRAMMING μPD8755A

Erasure of the μPD8755A occurs when exposed to ultraviolet light sources of wavelengths less than 4000 Å. It is recommended, if the device is exposed to room fluorescent lighting or direct sunlight, that opaque labels be placed over the window to prevent exposure. To erase, expose the device to ultraviolet light at 2537 Å at a minimum of 15 W-sec/cm^2 (intensity X expose time). After erasure, all bits are in the logic 1 state. Logic 0's must be selectively programmed into the desired locations. It is recommended that NEC's prom programmer be used for this application.

BIT-SLICE BIPOLAR MICROPROCESSOR

Bit slice microprocessors are most often used for design of Mini and Micro CPU s where a significant amount of arithmetic processing capability is desired or where highly parallel data processing is desired, such as signal processing.

FIXED-INSTRUCTION BIPOLAR MICROPROCESSOR

Fixed instruction processors, designed for specific problem solving, are most cost effective in this use. For example, Signetics 8X300 is specifically designed to efficiently implement high speed control oriented operations. For these applications, such as double density floppy disc controllers, CRT controllers, data communications controllers, and industrial controllers, the 8X300 is more cost effective than bit slice and, in some cases, MOS controllers.

©IC MASTER 1979

BIT SLICE MICROPROCESSORS

Bit slice components are generally used as building blocks for the central processing unit (CPU). Bit slices are used when high speed arithmetic processing is a prime requirement.

DESCRIPTION

The Signetics Micro Assembler is a complete software package used to design and program with Signetics bipolar bit-slice microprocessors. It contains advanced features to ease microprogramming and documentation.

The Micro Assembly language can be tailored to the configuration of the microprogram. It is designed especially for the Signetics bipolar microprocessors such as the 8X02 microprogram control sequencer, the 2900 microporcessor family, and the 3000 series. This flexibility enables it to handle virtually all microprogramming applications and microprocessor circuits.

The Micro Assembler consists of two interrelated programs. (See Figure 1)

The *Micro Assembly Program* reads the program system configurations and format descriptions to produce a listing of the source program and the resulting machine (binary) language. This listing contains source program error diagnostics and a cross-reference of microprogramming symbols.

The *Micro Format Program* translates the object program for direct use in programming PROMs. It reads the object program produced by the Micro Assembly Program and divides the object program into bits to be written into PROM modules, with separate output for each PROM.

FEATURES

- **High-level syntax—easy to use**
- **Cross reference listing**
- **Number of bits: Up to 4095 bits wide (default = 128)**
- **Number of instructions: Up to 65K words**
- **Mnemonic names and size of each control field**
- **Mnemonic names for control field values**
- **Organization of Micro Control Store as physical prom modules**
- **Formatting of object module for output**
- **Free-form input: Multiple statements per line**
- **Detection of overlapping fields for extensive error checking**
- **Multiple microinstruction formats: Variable microinstruction widths**
  - **Definition of sub-fields**
  - **Definition of more than one microinstruction thru multiple microinstruction Def. Sections**
- **Logical and relational expression operators**
- **Generation of non-microinstruction Proms (Look-up tables, mask generation, field expansion)**
- **Microp defaults under user definition**
- **Microp arguments**
- **Conditional (IF, THEN, ELSE) clause for field assignment and reference of microps**
- **Constants—Numeric and ASCII characters**
- **Nested microps**
- **Shift operators**

MICRO ASSEMBLY LANGUAGE

The Micro Assembly Language input into the assembler is divided into two sections:

The *definition* section defines instruction formats and device configurations of the user system. The name and length of each field is specified and symbolic opcodes are defined. Microinstructions may be any length, and multiple formats may be defined.

The *microprogram* section is the sequence of symbolic microinstructions that make up the operational program.

The Micro Assembly language also contains standard assembler directives and arithmetic, binary shift and logical operators.

Values used with the language may be decimal, hexadecimal, octal binary or ASCII character constants or symbolic values.

PROM FORMATTING

The format command file of the Micro Format Program translates the object program for PROM programming. Each bit of microinstruction, complemented or uncomplemented is identified with a PROM. The Microprogram addressing space may also be divided into bits and stored in PROM. There are provisions for inverted addresses. In a typical application, for example, microprogram may be distributed among ten 512x8 PROMs.

Among the output formats are: SMS, various BNPF formats, and 2650 absolute object code.

A full description is contained in the Signetics Micro Assembler Reference Manual.

AVAILABILITY

The Micro Assembler is written in ANSI FORTRAN IV. The source form is available on magnetic tape from Signetics in two formats:

- EBCDIC 9-track magnetic tape, unblocked 80-character records, 800 bpi density. Order part number 8X00MA1000SS.
- ASCII 9-track magnetic tape, unblocked 80-character records, 1600 bpi density. Order part number 8X00MA2000SS.

The Micro Assembler is also available on the more popular timesharing services.

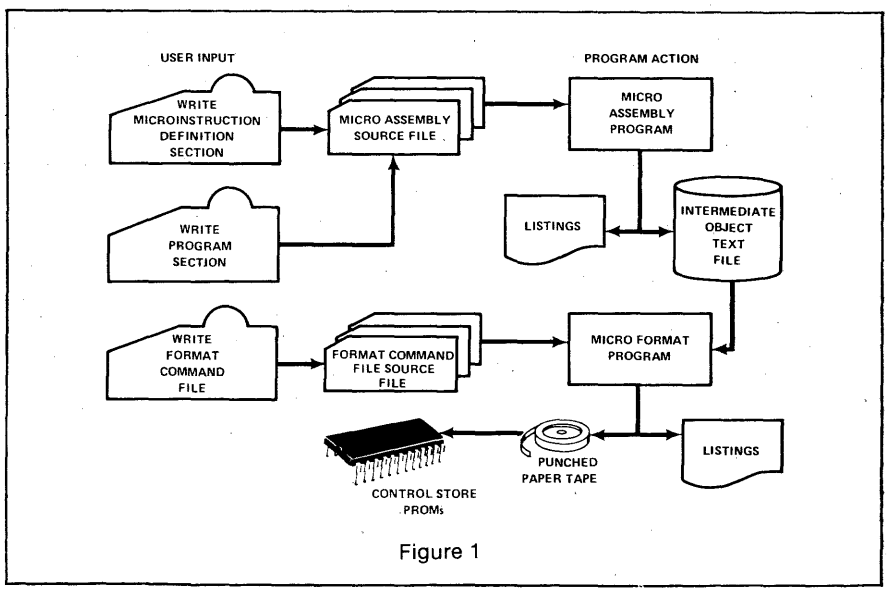

Figure 1

©IC MASTER 1979

DESCRIPTION

The 8X300 Assembler is a program which accepts source code written in the 8X300 assembly language and which produces both a listing of the symbolic program and an object module in one of four formats: MCSIM, ROM simulator, BPNF, or hexadecimal.

The assembler program is written in ANSI standard FORTRAN and is approximately 3000 card images in length. It requires some rewindable I/O medium such as disk or tape for temporary storage, an input device to read source code, and two output devices, one to output the assembler listing and one to output the object module. If desired, the assembler may be compiled and linked to execute in overlays.

The assembler consists of two passes which build a symbol table, issue helpful error messages, produce an easily readable program listing, and output a computer readable object module.

FEATURES

- **Macro nested to three levels**
- **Conditional assembly**
- **Address arithmetic**
- **Automatic procedure/subroutine handling**
- **Reserved symbols for registers**
- **Multiple entry to procedures**
- **Symbolic machine operation codes**
- **Symbolic assignment address references**
- **Symbolic data creation statements (I/O port reference)**
- **Free format source code**
- **Syntax error checking**
- **Self-defining constants**
- **Assembly listing control statements**
- **ASCII character code**
- **Comment statements and comment areas**
- **Forward referencing**
- **Cross-reference of the symbol table**
- **Instructions up to 32-bits wide**
- **Versatile object file format specification**

MCCAP LANGUAGE

The assembler recognizes three types of statements: Comment statements, machine instructions, and pseudo-ops (directives).

Comment statements are used to document a listing. They must contain an asterisk in column 1 and may contain any legal character in the other 79 columns.

Machine instruction statements are those statements that generate instruction(s) to be executed by the 8X300 processor. Machine instruction statements include:

MOVE	Move byte from one location to another.
ADD	Add the byte in one location to the byte in the auxiliary register and store the result in another location
AND	AND the byte in one location with the byte in the auxiliary register and store the result in another location.
XOR	Exclusive OR the byte in one location with the byte in the auxiliary register and store the result in another location.
XEC	Execute the instruction at the specified address.
XMIT	Transmit the literal (immediate data) contained in this instruction to the specified location.
NZT	Jump to the specified address if the value in the specified location is not zero.
JMP	Jump to the specified address.
CALL	Transfer control to a procedure or an entry point.
RTN	Returns control from a procedure or an entry point.
SEL	Places the address of an IV Byte variable into the IVL or the IVR register.
HALT	Halts by jump to current address.
NOP	Generates a no-op.

Pseudo-Ops (or Directives) are commands to the assembler, but have no meaning to the 8X300 processor.

EQU	Assigns a value to the symbol in the label field.
SET	Identical to EQU, except that the symbol may be redefined by another SET statement.
LIV	Assigns a symbolic name to the address, position and precision of the "left bank" Interface Vector Byte variable.
RIV	Identical to LIV, except that the assignment is made to the "right bank" I/O Field.
PROG	Introduces and names the main program.
PROC	Introduces and names a procedure.
ENTRY	Specifies an additional entry point to a procedure.
END	Terminates a procedure, a program or a MACRO.
ORG	Changes the value of the location counter.
OBJ	Specifies the format of the object module.
IF	Introduces source statements subject to conditional assembly.
ENDIF	Terminates the source statements subject to conditional assembly.

LIST	Specifies the list and punch options.
NLIST	Negates the list and punch options.
EJCT	Advances listing to next page.
SPAC	Advances listing to next line.
MACRO	Defines the source statements generated a macro call.
PROM	Specifies the size of the object module.
DEF	Defines extended instruction fields.

The assembler produces object code for the 8X300 and for extended instructions. Extended instructions are bit patterns that are selected at the same time as the standard 8X300 instructions and are used for hardware selection of I/O ports or working storage, thereby reducing program length and increasing throughput.

A full description of MCCAP is contained in the Signetics Microcontroller Cross-Assembly Program Manual.

AVAILABILITY

The assembler is available on the more popular timesharing services. It is also available from Signetics on 9-track magnetic tape in the following formats.

- EBCDIC unblocked 80-character records, 800 bpi density. Order part number 8X300AS100SS.
- ASCII blocked 80-character records, 1600 bpi density. Order part number 8X300AS200SS.

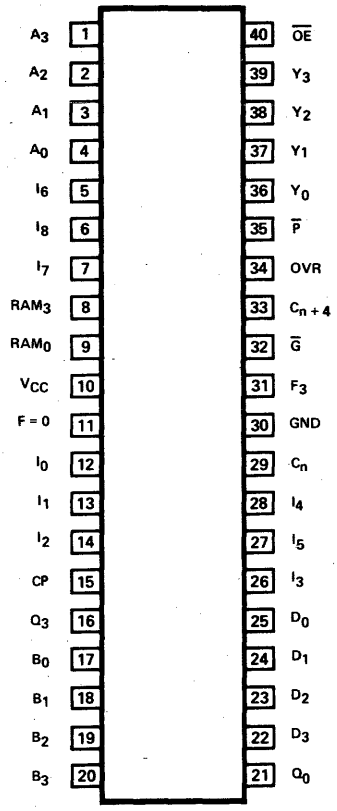
Signetics

©IC MASTER 1979

N2901A

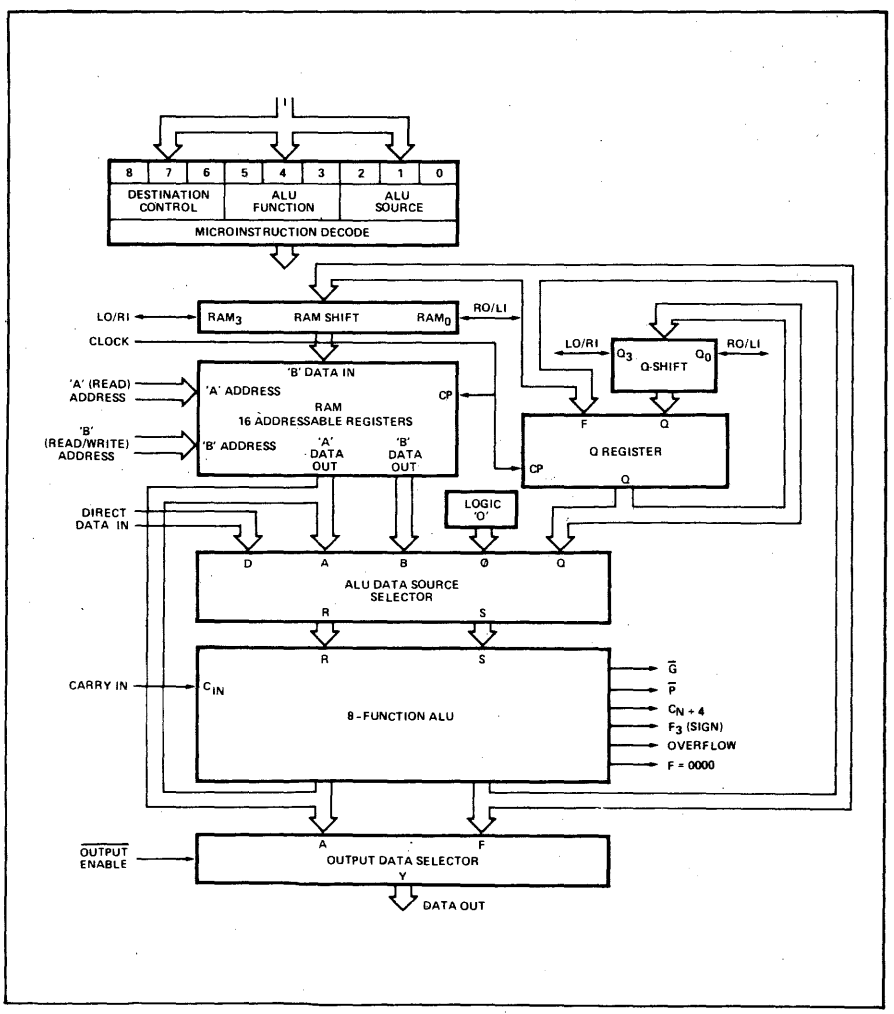
DESCRIPTION

The 4-bit bipolar microprocessor slice is designed as a high-speed cascadable element intended for use in CPUs, peripheral controllers, programmable microprocessors and numerous other applications. The microinstruction flexibility of the 2901A will allow efficient emulation of almost any digital computing machine.



The device, as shown in the block diagram below, consists of a 16-word by 4-bit 2-port RAM, a high-speed ALU, and the associated shifting, decoding and multiplexing circuitry. The 9-bit microinstruction word is organized into 3 groups of 3 bits each and selects the ALU source operands, the ALU function, and the ALU destination register. The microprocessor is cascadable with full look-ahead or with ripple carry, has three-state outputs, and provides various status flag outputs from the ALU. Advanced low-power Schottky processing is used to fabricate this 40-lead LSI chip.

FEATURES



- **80ns cycle time**
- **2-address architecture**
  Independent simultaneous access to 2 working registers saves machine cycles
- **8-function ALU**
  Performs addition, 2 subtraction operations, and 5 logic functions on 2 source operands
- **Flexible data source selection**
  ALU data is selected from 5 source ports for a total of 203 source operand pairs for every ALU function
- **Left/right shift independent of ALU**
  Add and shift operations take only 1 cycle
- **4 status flags**
  Carry, overflow, zero, and negative
- **Expandable**
  Connect any number of 2901A's together for longer word lengths.
- **Microprogrammable**
  3 groups of 3 bits each for source operand, ALU function, and destination control

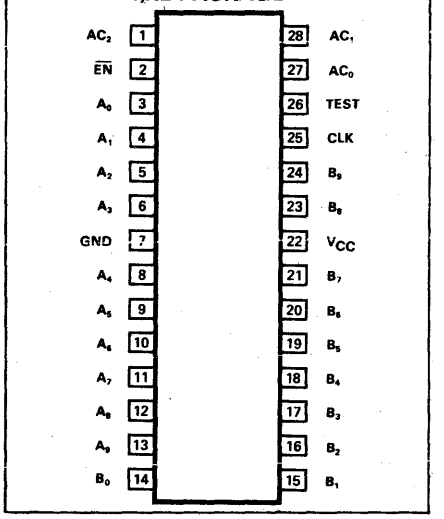
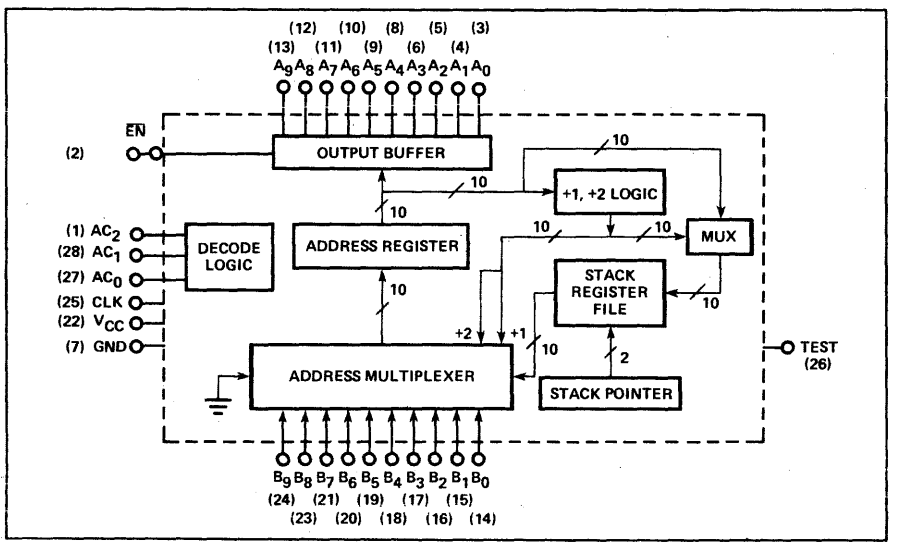
8X02-I,XL

DESCRIPTION



The Signetics 8X02 is a low power Schottky LSI device intended for use in high performance microprogrammed systems to control the fetch sequence of microinstructions. When combined with standard ROM or PROM, the 8X02 forms a powerful microprogrammed control section for computers, controllers, or sequential logic.

FEATURES



- **Low power Schottky process**
- **1024 microinstruction addressability**
- **N-way branch**
- **4-level stack register file (LIFO type)**
- **Automatic push/pop stack operation**
- **"Test and skip" operation on test input line**
- **3-bit command code**
- **Tri-state buffered outputs**
- **Auto-reset to address 0 during power-up**
- **Conditional branching, pop stack, and push stack**

FUNCTIONAL DESCRIPTION

The Signetics 8X02 Control Store Sequencer is an LSI device using low power Schottky technology and is intended for use in high performance microprogrammed applications. When used alone, the 8X02 is capable of addressing up to 1K words of microprogram. This may be expanded to any microprogram size by conventional paging techniques.

The Address Register consists of 10 D-type, edge-triggered flip-flops with a common clock. A new address is entered into the Address Register on the low-to-high transition of the clock. The next address to be entered into the Address Register is supplied via the Address Multiplexer.

The Address Multiplexer is a 5-input device that is used to select either the branch input, +1 adder, +2 adder, stack register file, or ground (all zeros) as the source of the next microinstruction address. The proper multiplexer channel is automatically selected via the Decode Logic according to the Address Control Function Input and Test Input line.

The +1, +2 logic is used to increment the present contents of the Address Register by 1 or 2, depending on the function input command. Thus, the next address to the Control Store ROM/PROM may be either the current address plus 1 (N+1) or the current address plus 2 (N+2). If the same Microprogram Address is to be used on successive occasions, the clock to the 8X02 must simply be disabled; therefore, no new address is loaded into the Address Register.

The Stack File Register is used to provide a return address linkage whenever a subroutine or loop is executed. The 4X10 stack operates in a last-in, first-out (LIFO) mode, with the stack pointer always pointing to the next address to be read. Operation of the stack pointer is automatically controlled by the Address Control Function Inputs. Since the stack is 4 words deep, up to 4 loops and/or subroutines may be nested.

The stack pointer operates as an up/down counter. The stack pointer is incremented by one during the PUSH operation. The new data is written into the new location pointed to by the stack pointer. A POP operation will read data from the location pointed to by the stack pointer in the previous cycle, and the stack pointer will be decremented by one at the end of the current cycle. When the stack pointer is pointing at the first level of the stack, a POP operation will cause the stack pointer to wrap around to the fourth level of the stack. Similarly, a PUSH operation will cause the stack pointer, when pointing at the fourth level of the stack to wrap around to the first level of the stack.

The branch input is a 10-bit field of direct inputs to the multiplexer which can be selected as the next control store address. Using the appropriate branch command, an N-way branch is possible where N is the address of any microinstruction within the 1024 word microcode page. Likewise, the RESET command is a special case of an N-way branch in which the multiplexer selects an all zeros input, forcing the next microinstruction address to be zero.

The Test Input line is used in conjunction with the conditional execution of 4 Address Control Function commands. When the Test Input is false (low), the sequencer simply increments to the next address (N+1). When it is true (high), the sequencer executes a branch as defined by the input command, thereby transferring control to another portion of the microprogram.

All Address Output lines of the 8X02 are three-state buffered outputs with a common enable line ($\overline{EN}$). When the Enable line is high, all outputs are placed in a high-impedance state, and external access to the control store ROM/PROM is possible. This allows a preprogrammed set of microinstructions to be executed from external or built-in test equipment (BITE), vectored interrupts, and Writable Control Store if implemented.

NEXT ADDRESS CONTROL FUNCTION TABLE

MNEMONIC	DESCRIPTION	FUNCTION AC_2 1 0	TEST	NEXT ADDRESS	STACK	STACK POINTER

©IC MASTER 1979

DESCRIPTION

The Signetics 8X300 Microcontroller is a monolithic, high-speed microprocessor implemented with bipolar Schottky technology. As the central processing unit, CPU, it allows 16-bit instructions to be fetched, decoded and executed in 250ns. A 250ns instruction cycle requires maximum memory access of 65ns, and maximum I/O device access of 35ns.

Microcontroller instructions operate on 8-bit, parallel data. Logic is distributed along the data path within the Microcontroller. Input data can be rotated and masked before being subject to an arithmetic or logical operation; and output data can be shifted and merged with the input data, before being output to external logic. This allows 1- to 8-bit I/O and data memory fields to be accessed and processed in a single instruction cycle.

PROGRAM STORAGE INTERFACE

Program Storage is typically connected to the A0-A12 (A12 is least significant bit) and I0-I15 signal lines. An address output on A0-A12 identifies one 16-bit instruction word in program storage. The instruction word is subsequently input on I0-I15 and defines the Microcontroller operations which are to follow.

The Signetics 82S115 PROM, or any TTL compatible memory, may be used for program storage.

I/O DEVICES INTERFACE

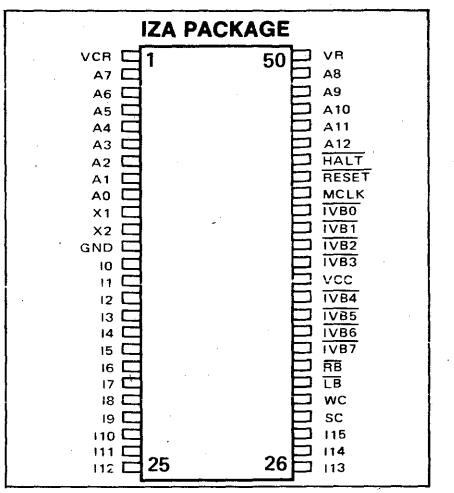
An 8-bit I/O bus, called the Interface Vector (IV) data bus, is used by the Microcontroller to communicate with 2 fields of I/O devices. The complementary $\overline{LB}$ and $\overline{RB}$ signals identify which field of the I/O devices is selected.

Both I/O data and I/O address information can be output on the IV bus. The SC and WC signals are typically used to distinguish between I/O data and I/O address information as follows:

SC	WC	
1	0	I/O address is being output on IV bus
0	1	I/O data is being output on IV bus
0	0	I/O data is expected on the IV, bus, as input to the Microcontroller
1	1	Not generated by the Microcontroller

The Signetics 82SXXX series RAM, and the 8T32/33 may be attached to the IV bus.

FEATURES



- **185ns instruction decode and execute delay (with Signetics 8T32/33 I/O port)**
- **Eight 8-bit working registers**
- **Single instruction access to 1-bit, 2-bit, 3-bit or 8-bit field on I/O bus**
- **Separate instruction address, instruction, and I/O data buses**
- **On-chip oscillator**
- **Bipolar Schottky technology**
- **TTL inputs and outputs**
- **Tri-state output on I/O data bus**
- **+5 volt operation from 0° to 70°C**

MILITARY

Also available in Military version as S8X300-1 or S8X300-2

PIN CONFIGURATION

IZA PACKAGE

PIN DESIGNATION

PIN	SYMBOL	NAME AND FUNCTION	TYPE
2-9, 45-49	A0-A12:	Instruction address lines. A high level equals "1." These outputs directly address up to 8192 words of program storage. A12 is least significant bit.	Active high
13-28	I0-I15:	Instruction lines. A high level equals "1." Receives instructions from Program Storage. I_{15} is least significant bit.	Active high
33-36, 38-41	$\overline{IVB0}$-$\overline{IVB7}$	Interface Vector (IV) Bus. A low level equals "1." Bidirectional tri-state lines to communicate with I/O devices. $\overline{IVB7}$ is least significant bit.	Three-state Active low
42	MCLK:	Master Clock. Output to clock I/O devices, and/or provide synchronization for external logic	Active high
30	WC:	Write Command. High level output indicates data is being output on the IV Bus.	Active high
29	SC:	Select Command. High level output indicates that an address is being output on the IV Bus.	Active high
31	$\overline{LB}$:	Left Bank. Low level output to enable one of two sets of I/O devices ($\overline{LB}$ is the complement of RB).	Active low
32	$\overline{RB}$:	Right Bank. Low level output to enable one of two sets of I/O devices ($\overline{RB}$ is the complement of $\overline{LB}$).	Active low
44	$\overline{HALT}$:	Low level is input to stop the Microcontroller.	Active low
43	$\overline{RESET}$:	Low level is input to initialize the Microcontroller.	Active low
10-11	X1, X2:	Inputs for an external frequency determining crystal. May also be interfaced to logic or test equipment.	
50	VR	Reference voltage to pass transistor.	
1	VCR	Regulated output voltage from pass transistor.	
37	V_{CC}:	5V power connection.	
12	GND:	Ground.

MICROCONTROLLER ARCHITECTURE

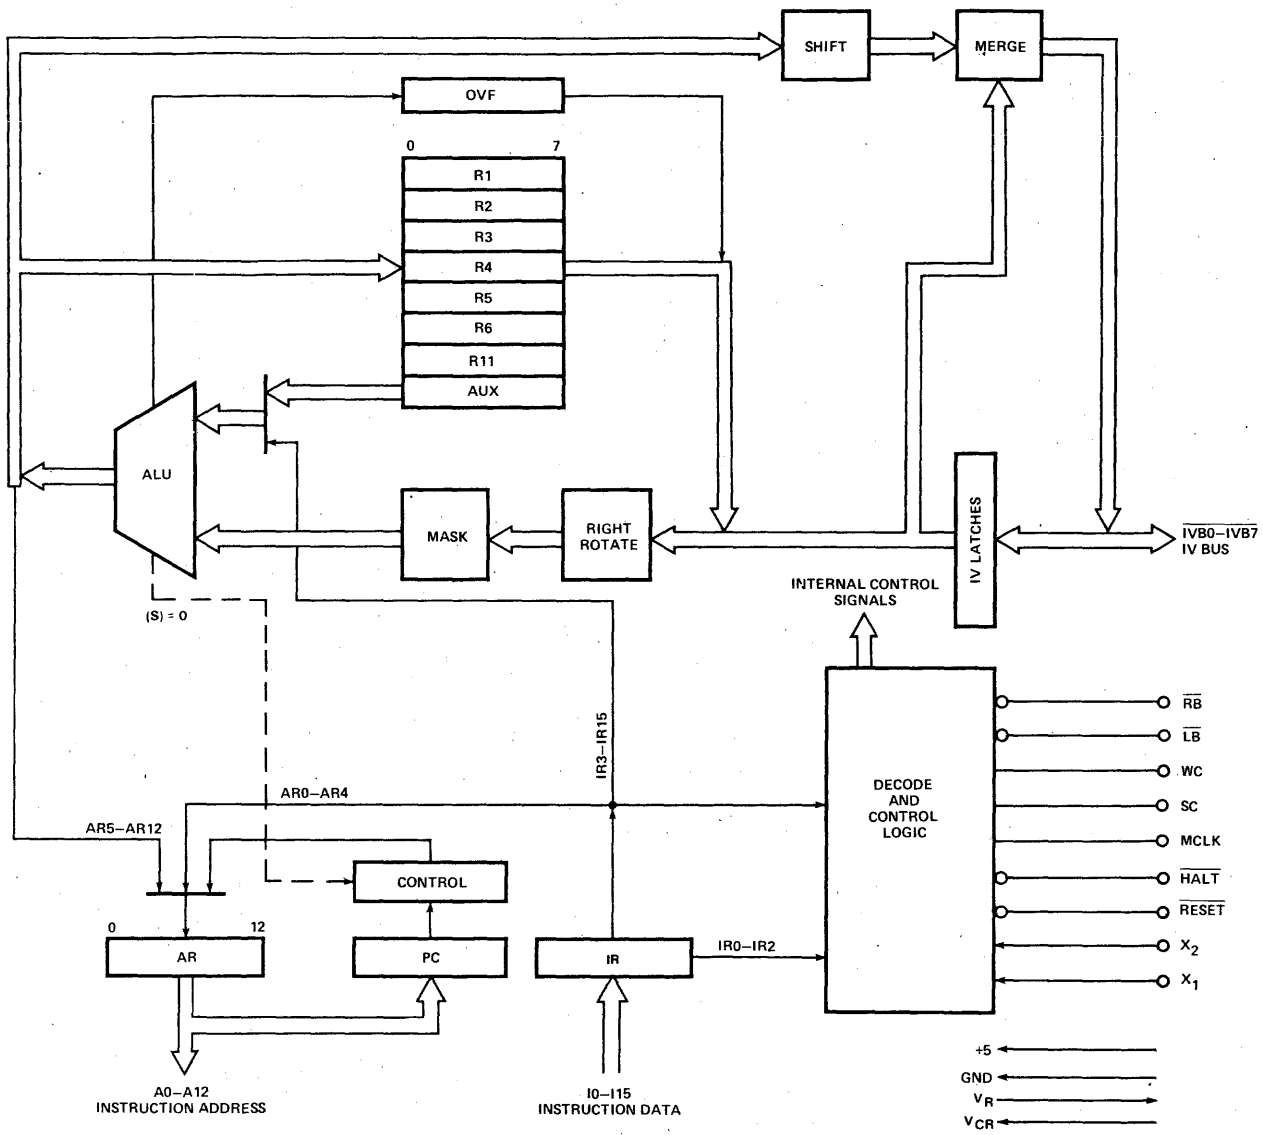

Figure 1

R1 — General working register
R2 — General working register
R3 — General working register
R4 — General working register
R5 — General working register
R6 — General working register
R11 — General working register
AUX — General working register. Contains second term for arithmetic or logical operations.

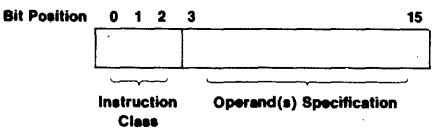
OVF — The least-significant bit of this register is used to reflect overflow status resulting from the most recent ADD operation (see Instruction Set Summary).

Instruction Register (IR)
— Holds the 16-bit instruction word currently being executed.

Program Counter (PC)
— Normally contains the address of the current instruction and is incremented to obtain the next instruction address.

Address Register (AR)
— A 13-bit register containing the address of the current instruction.

Table 1 INTERNAL REGISTERS



INSTRUCTION CYCLE

Each Microcontroller operation is executed in 1 instruction cycle, which may be as short as 250ns. The Microcontroller generates MCLK to synchronize external logic to the instruction cycle. Instruction cycles are subdivided into quarter cycles. MCLK is an output during the last quarter cycle.

During the third quarter cycle of an instruction, an address is output on A0-A12, identifying the location in program storage of the next instruction word. This instruction word defines the next instruction, which must be input on I0-I15 during the first quarter cycle of the next instruction cycle (see Table 2).

Instruction Set Summary

The 16-bit instruction word input on I0-I15 is decoded by the instruction decode logic to implement events that are to occur during the remainder of the instruction cycle. Generally the 16-bit instruction word is decoded as follows:

A detailed usage of the 13 "operand(s) specification" bits is given in following sections.

Three operation code bits allow for 8 instruction classes. The 8 instruction classes are summarized in Table 3. Each entry is referred to as an "instruction class" because the unique architecture of the Interpreter allows a number of powerful variations to be specified by the 13 operand(s) specification bits. A complete description of instruction formats and some instruction examples are provided in the Microprocessor Applications manual.

Data Processing

The Microcontroller architecture includes eight 8-bit working registers, an arithmetic logic unit (ALU), an overflow register, and the 8-bit IV Bus. Internal 8-bit data paths connect the registers and IV Bus to the ALU inputs, and the ALU output to the registers and IV Bus. Data processing logic is distributed along these internal 8-bit data paths. Rotate and mask logic precedes the ALU on the data entry path. Shift and merge logic follows the ALU on the data output path. All 4 sets of logic can operate on 8 data bits in a single instruction cycle (See Figure 1).

When less than 8 bits of data are specified for output to the IV bus by the ALU, the data field (shifted if necessary) is inserted into the prior contents of the IV bus latches. The IV bus latches contain data input at the start of an instruction. This data in the IV bus latches will be specified in the instruction as a) IV bus source data or b) data from an automatic read when the IV bus is specified as a destination. Therefore, IV bus bit positions outside an inserted bit field are unmodified.

Data Addressing

Sources and destinations of data are specified using a 5-bit octal number. The source and/or destination of data to be operated upon is specified in a single instruction word.

Referring to Figure 1, the Auxiliary register (address 00) is the implied source of the second argument for ADD, AND or XOR operations.

IVL and IVR are write-only registers used only as a destination. They have addresses and are treated as registers, but in reality they do not exist. When IVL is specified as a destination or the D field = $20\text{-}27_8$, then LB = 'low', RB = 'high' are generated; when IVR is specified as a destination or the D field = $30\text{-}37_8$, then RB = low, LB = 'high' are generated.

When IVL or IVR is specified as the destination in an instruction, SC is also activated and data is placed on the IV bus. If IVL or IVR is specified as a source of data, the source data is all zeroes.

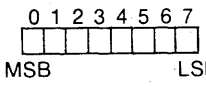
Table 2 INSTRUCTION CYCLE

INSTRUCTION SEQUENCE CONTROL

The Address Register and Program Counter are used to generate addresses for accessing an instruction. The Address Register is used to form the instruction address, and in all but 3 instructions (XEC, NZT, and JMP) the address is copied into the Program Counter. The instruction address is formed in 1 of 3 ways:



1. For all instructions but the JMP, XEC, and a satisfied NZT, the Program Counter is incremented by 1 and placed in the Address Register.
2. For the JMP instruction, the full 13-bit address field from the JMP instruction is placed into the Address Register and copied into the Program Counter.
3. For the XEC and NZT instructions, the high order 5- or 8-bits of the Program Counter are combined with 8- or 5-lower-order bits of ALU output (XEC or NZT) and placed in the Address Register. For the NZT instruction, it is also copied into the Program Counter.

©IC MASTER 1979

INSTRUCTION SET

The 8X300 Microcontroller has a repertoire of 8 instruction classes which allow the user to test input status lines, set or reset output control lines, and perform high speed input/output data transfers. All instructions are 16 bits in length and each is fetched, decoded and executed in 250ns.

Data is respresented as an 8-bit byte; bit positions are numbered from left to right, with the least significant bit in position 7.

Within the 8X300, all operations are performed on 8-bit bytes. Arithmetic operations use 8-bit, unsigned 2's complement arithmetic.

INSTRUCTION FORMATS

The general 8X300 instruction format is:

0 1 2	3 4 5 6 7 8 9 10 11 12 13 14 15
Op Code	Operand(s)

All instructions are specified by a 3-bit Operation (Op Code) field. The operand may consist of the following fields: Source (S) field, Destination (D) field, Rotate/Length (R/L) field, Immediate (I) field, or (Program Storage) Address (A) field.

The instructions are divided into 5 format types, based on the Op Code and the Operand(s), as shown in Figure 3.

OPERATION	FORMAT	RESULT	NOTES
MOVE	I,II	Content of data field specified by {S, R/L} replaces data in field specified by {D, R/L.}	If S and D both are registers, then R/L specifies a right rotate of the register specified by S.
ADD	I,II	Sum of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L}.	
AND	I,II	Logical AND of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L.}	
XOR	I,II	Logical exclusive OR of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L.}	
XMIT	III,IV	The literal value I replaces the data in the field specified by {S,L.}	If S is an I/O address then I is limited to range 00-37. Otherwise I is limited to range 000-377.
NZT	III,IV	If the data in the field specified by {S, L} equals zero, perform the next instruction in sequence. If the data specified by {S,L} is not equal to zero, execute the instruction at address determined by using the literal I as an offset to the Program Counter.	If S is an I/O address then I is limited to range 00-37. Otherwise I is limited to range 000-377.
XEC	III,IV	Perform the instruction at address determined by applying the sum of the literal I and the data specified by {S, L} as an offset to the Program Counter. If that instruction does not transfer control, the program sequence will continue from the XEC instruction location.	The offset operation is performed by reducing the value of PC to the nearest multiple of 32 (if I = 00-37) or 256 (if I = 000-377) and adding the offset.
JMP	V	The address value A replaces contents of the Program Counter.	A limited to the range 0-17777$_8$.

SYSTEM DESIGN USING THE 8X300 MICROCONTROLLER

Designing hardware around the 8X300 Interpreter reduces to selecting a program storage devicer (ROM, PROM, etc.), selecting I/O devices (IV byte, multiplexers, RAM, etc.), selecting clock mode (system driven or crystal controlled) and interfacing the Microcontroller to these components.

A specific example of a control system using the 8X300 Microcontroller is shown in Figure 12. Only 8 components—four 8T32 I/O Ports, one 8X350 RAM, two 82S215 ROMs, and an 8X300 are required to build this system which contains 512 words of program storage, 32 TTL I/O connection points, 256 bytes of working storage, and operates at a 250ns instruction cycle time.

Halt, Reset Signals

$\overline{\text{HALT}}$:
A low level at the $\overline{\text{HALT}}$ input stops internal operation of the Microcontroller at the start of the next instruction after $\overline{\text{HALT}}$ is applied (quarter cycle after MCLK). Since $\overline{\text{HALT}}$ is sampled at the start of each instruction cycle it is possible to prevent a cycle by applying $\overline{\text{HALT}}$ early in that cycle. $\overline{\text{HALT}}$ does not inhibit MCLK or affect any internal registers. Normal operation begins with the next complete cycle after the $\overline{\text{HALT}}$ input goes high.

$\overline{\text{RESET}}$:
A low level at the $\overline{\text{RESET}}$ input sets the program counter and address register to zero. While $\overline{\text{RESET}}$ is low MCLK is inhibited. If $\overline{\text{RESET}}$ is applied during the last 2 quarter cycles, the MCLK during that cycle may be shortened. $\overline{\text{RESET}}$ should be applied for 1 full instruction cycle time to assure proper operation. When $\overline{\text{RESET}}$ input goes high an MCLK occurs prior to the resumption of normal processing. $\overline{\text{RESET}}$ does not affect the other internal registers.

SYSTEM TIMING

In systems with fast instruction cycle times, most Microcontroller delays are strictly determined by internal gate propagation delays.

EXAMPLE OF CONTROL SYSTEM

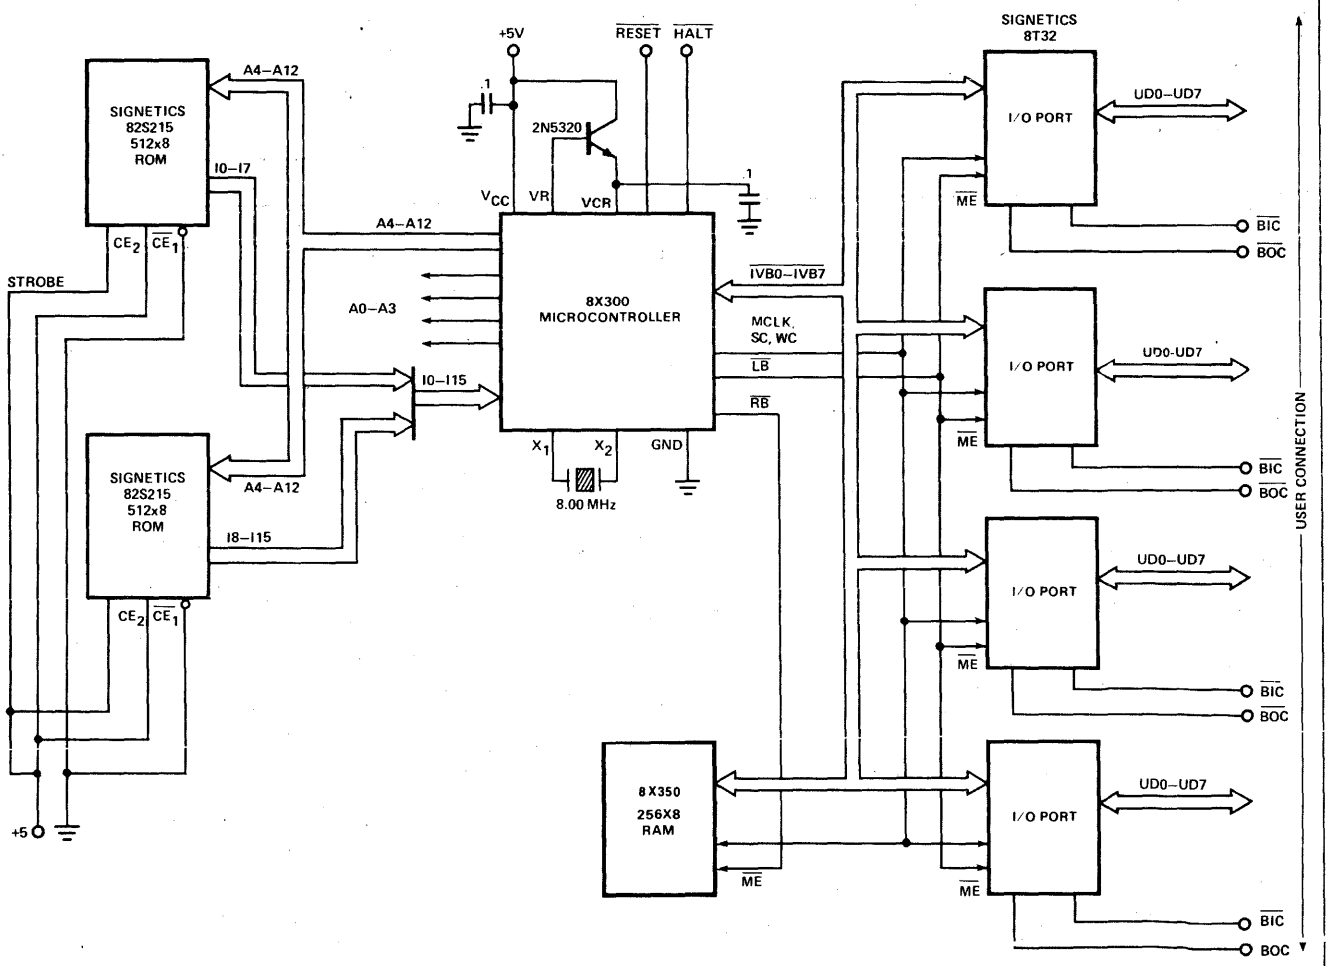

Figure 12

©IC MASTER 1979

Since some events are constrained to occur in certain quarter cycles, as system cycle times become slower, the delays will appear to increase due to gating with internal clocks. In the table of AC Electrical Characteristics, 2 columns are used: 1 to denote times which occur due to internal clock intervention and 1 to denote minimum delays for fast cycle times.

When using Signetics 8T32 I/O Ports, selection of instruction cycle time involves calculating the maximum program storage access time. Assuming the instruction is available when MCLK falls, the I/O control lines are stable 35ns later. Signetics 8T32's require another 35ns to disable a previously selected port and enable the desired port (assumes a change in bank signals). A 10ns margin has been added to the 8T32 enable for this evaluation to reflect the fact that most systems will have more capacitive loading than the 50pF test condition in the 8T32 specification and to allow for line delays.

The system instruction cycle time for normal systems such as shown in Figure 12 is determined by Microcontroller propagation delays, program storage access time, and port output enable times. Instruction cycle time is normally constrained by one or more of the following conditions:

1. Instruction to LB/RB (input phase) + I/O Port output enable: $T_{OE} \leq$ ½cycle - 55ns (Figure 13).
2. Program storage access time + instruction to LB/RB (input phase) + I/O Port output enable and IV data (input phase) to address ≤ instruction cycle time (Figure 14).
3. Program storage access time + instruction to address ≤ instruction cycle time (Figure 15).

The first constraint can be used to determine the minimum cycle time. Using the inequality 35ns + 35ns ≤ ½ cycle - 55ns implies ½ cycle ≥ 125ns or an instruction time of 250ns.

Program storage access time for a 250ns instruction cycle can be calculated from the second constraint. Noting that the specification for IV data (input phase) to address is 115ns: Program storage access time + 35ns + 35ns + 115ns ≤ 250ns implies program storage access time ≤ 65ns.

The third constraint can be used to verify the maximum program storage access time. Noting that the specification for instruction to address is 185ns: Program storage access time + 185ns ≤ 250ns confirms that program storage access time 65ns is satisfactory.

System Clock

The Micrcontroller has an integrated oscillator which generates all necessary clock signals. The oscillator is designed to connect directly to a series resonant quartz crystal via pins X1 and X2. The crystal resonant frequency, f, is related to the desired cycle time, T, by the relationship f = 2/T. For a 250ns system, f = 8.00MHz.

Type:	Fundamental mode, series resonant
Impedance at Fundamental:	35 ohms maximum
Impedance at harmonics and spurs:	50 ohms minimum

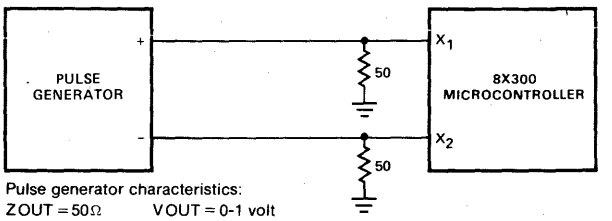

Table 7 CRYSTAL CHARACTERISTICS

In lower speed applications where the cycle time need not be precisely controlled, a capacitor may be connected between X1 and X2 to drive the oscillator. Approximate capacitor values are given in Table 8. If cycle time is to be varied, X1 and X2 should be driven from complementary outputs of a pulse generator. Figure 16 shows a typical configuration. For systems where the Interpreter is to be driven from a master clock the X1 and X2 lines may be interfaced to TTL logic as shown in Figure 17.

Cx,pF	CYCLE TIME
100	300ns

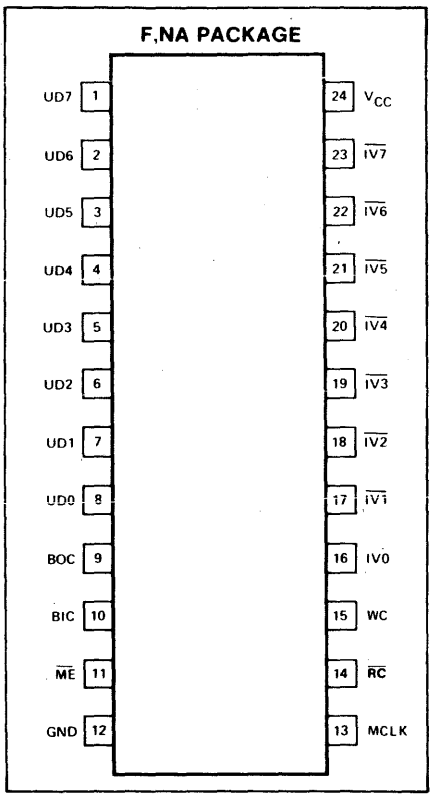
DESCRIPTION

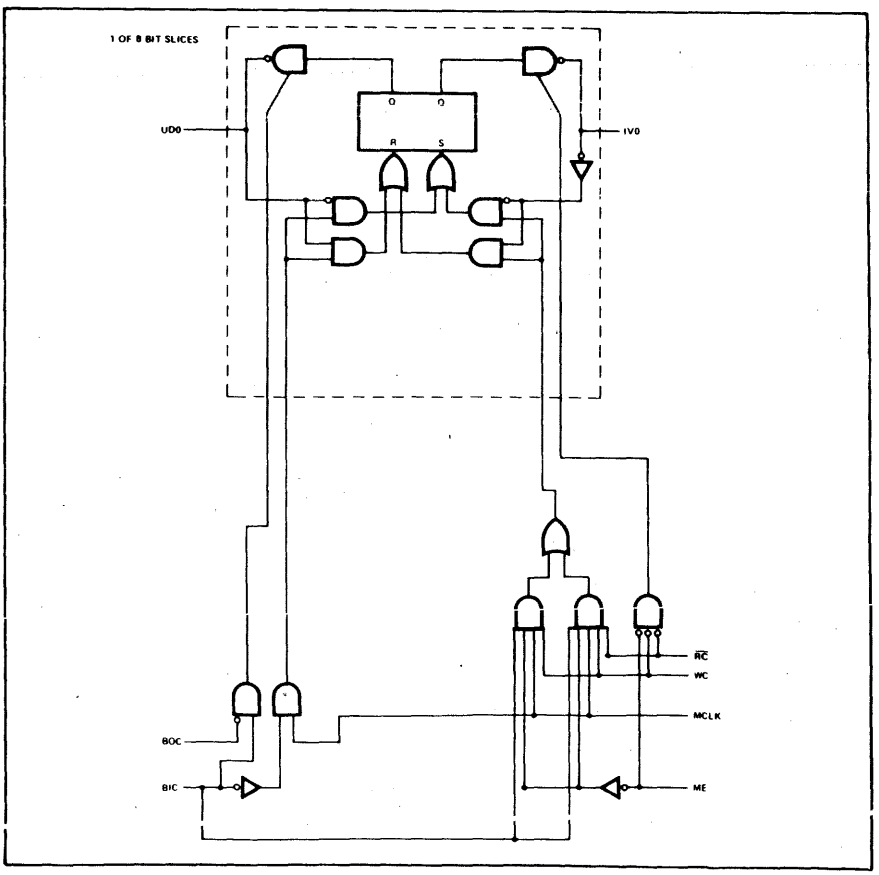
The I/O Port is an 8-bit bidirectional data register designed to function as an I/O interface element in microprocessor systems. It contains 8 clocked data latches accessible from either a microprocessor port or a user port. Separate I/O control is provided for each port. The 2 ports operate independently, except when both are attempting to input data into the I/O Port. In this case, the user port has priority.

A master enable (ME) is provided that enables or disables the μP bus regardless of the state of the other inputs, but has no effect on the user bus.



A unique feature of this family is its ability to start up in a predetermined state. If the clock is maintained at a voltage less than .8V until the power supply reaches 3.5V, the user port will always be all logic 1 levels, while the microprocessor port will be all logic 0 levels.

FEATURES



- **Each device has 2 ports, one to the user, the other to a microprocessor. I/O Ports are completely bidirectional**
- **Ports are independent, with the user port having priority for data entry**
- **User data input synchronous**
- **The user data bus is available with tri-state (8T32, 8T36) or open collector (8T33, 8T35) outputs**
- **At power up, the user port outputs are high**
- **Tri-state TTL outputs for high drive capability**
- **Directly compatible with the 8X300 Microcontroller**
- **Operates from a single 5V power supply over a temperature range of 0°C to +70°C**

TYPES

8T32 Tri-State, Synchronous User Port
8T33 Open Collector, Synchronous User Port
8T35 Open Collector, Asynchronous User Port
8T36 Tri-State, Asynchronous User Port

DESCRIPTION

The Addressable I/O Port is an 8-bit bidirectional data register designed to function as an I/O interface element in microprocessor systems. It contains 8 data latches accessible from either a microprocessor port or a user port. Separate I/O control is provided for each port. The 2 ports operate independently, except when both are attempting to input data into the I/O Port. In this case, the user port has priority.

A unique feature of the I/O Port is the way in which it is addressed. Each device has an 8-bit, field programmable address, which is used to enable the microprocessor port. When the SC control signal is high, data at the microprocessor port is treated as an address. If the address matches the I/O Port's internally programmed address, the microprocessor port is enabled, allowing data transfer through it.

The port remains enabled until an address which does not match is presented, at which time the port is disabled (data transfer is inhibited). A Master Enable input (ME) can serve as a ninth address bit, allowing 512 I/O Ports to be individually selected on a bus, without decoding. The user port is accessible at all times, independent of whether or not the microprocessor port is selected.

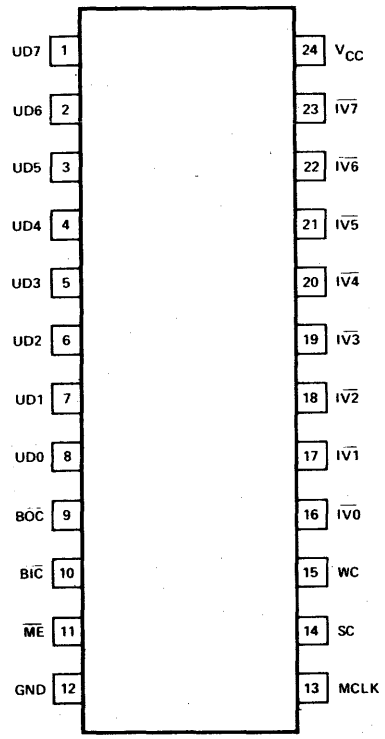
A unique feature of this family is their ability to start up in a predetermined state. If the clock is maintained at a voltage less than .8V until the power supply reaches 3.5V, the user port will always be all logic 1 levels, while the port will be all logic 0 levels.

ORDERING

The 8T32/33/35/36 may be ordered in preaddressed form. To order a preaddressed device use the following part number format:

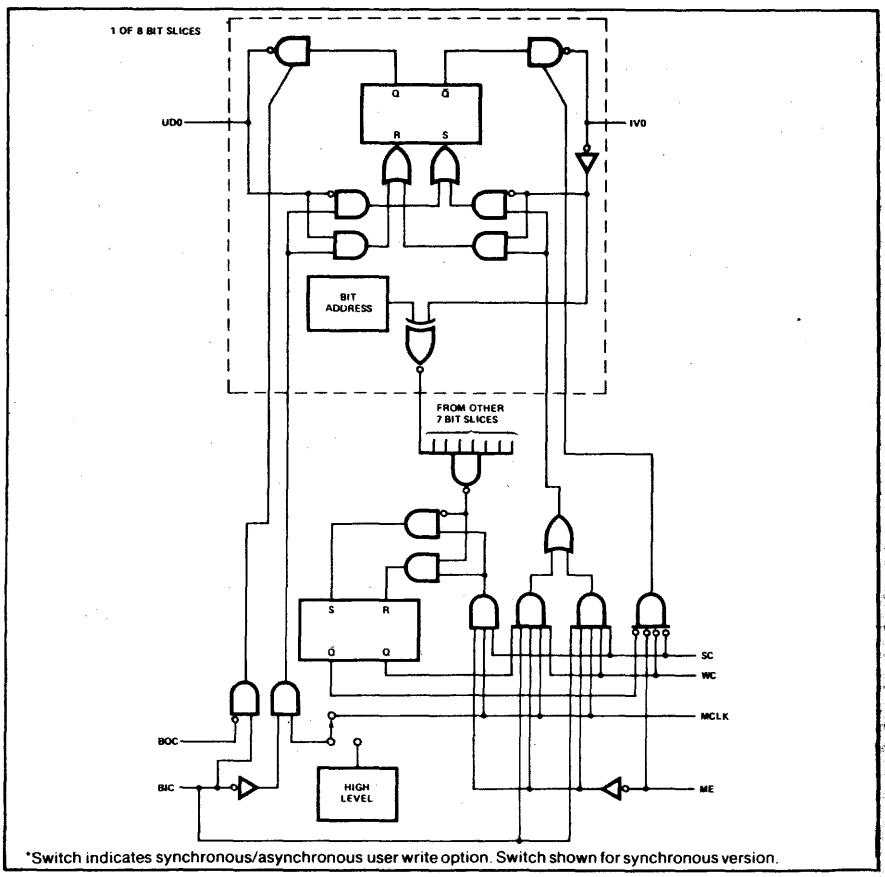
N8TYY-XXX P

- P = F Ceramic package, NA Plastic package
- XXX = Any address from 000 through 255 (decimal) - 256 available addresses
- YY = I/O Port version (32, 33, 35, 36)



A stock of 8T32s and 8T36s with addresses 1 through 10 will be maintained. A small quantity of addresses 11 through 50 will also be available with a longer lead time.

FEATURES



- **A field-programmable address allows 1 of 512 I/O Ports on a bus to be selected, without decoders.**
- **Each device has 2 ports, one to the user, the other to a microprocessor.**
- **Completely bidirectional.**
- **Ports are independent, with the user port having priority for data entry.**
- **A selected I/O Port de-selects itself when another I/O Port address is sensed.**
- **User data input available as synchronous (8T32, 8T33) or as asynchronous (8T35, 8T36) function.**
- **The user data bus is available with tri-state (8T32, 8T36) or open collector (8T33, 8T35) outputs.**
- **At power up, the I/O Port is not selected and the user port outputs are high.**
- **Tri-state TTL outputs for high drive capability.**
- **Directly compatible with the 8X300 Microcontroller.**
- **Operates from a single 5V power supply over a temperature range of 0° C to 70° C.**

PRELIMINARY SPECIFICATION 8T39-I,XL

DESCRIPTION

The Bus Expander is specifically designed to increase the I/O capability of 8X300 systems previously limited by fanout considerations. The bus expander serves as a buffer between the 8X300 and blocks of I/O devices. Each bus expander can buffer a block of 16 I/O ports while only adding a single load to the 8X300.

FEATURES

- **15ns max propagation delay**
- **Bidirectional**
- **Three-state outputs on both ports**
- **Pre-programmed address range**

APPLICATIONS

The 8T39 Bus Expander is designed to be used with the 8X300 microprocessor to allow increased I/O capability in those systems previously limited by fanout considerations. Figure 1 shows a typical arrangement of the bus expander in an 8X300 system. Each expander services I/O ports whose address is within the range of the expander. Other I/O ports or working storage may be directly connected to the bus as shown.

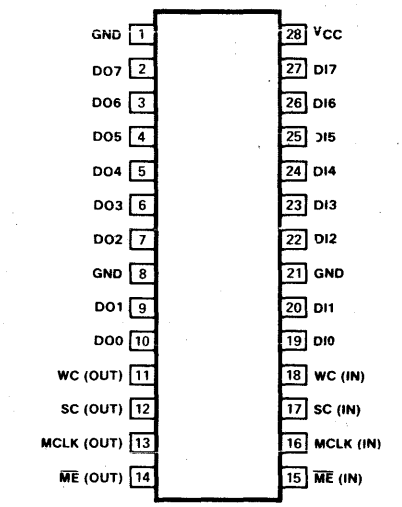
The bus expander is not limited to use with the 8X300, but may be applied in any system which uses a combined address/data bus.

8T39 ADDRESSING

During normal operation of the 8X300 when an I/O port address is being sent on the IV Bus (SC is high), the I/O port will examine all eight bits of the microprocessor bus for an address compare. Since the 8T39 is used to buffer blocks of I/O ports, only the four most significant bits are examined by the 8T39 for an address compare.

Note that redundant addresses are not programmed into separate devices. Rather, a discrete device (such as the 8T39-03) may be wired for any address requiring two 1 bits and two 0 bits in the address. The various address ranges for this same device are obtained by permuting the high order (DI0 and DO0 are MSB) data lines accordingly. Both input and output lines must be redefined in order to maintain data and address integrity on the extended bus. Table 1 summarizes the 8T39 addressing.

Address functions are specified with the convention that bit 0 is the MSB and bit 7 is the LSB. The DI microprocessor bus address decoding is active low.



FUNCTIONAL DESCRIPTION

The Bus Expander contains eight sets of non-inverting bidirectional tri-state drivers for the bus data bits, four non-inverting unidirectional drivers for I/O port control, and necessary control logic. The control logic is required to maintain the proper directional transfer of bus data as dictated by the states of the I/O port control signals and the currently enabled I/O port. Each bus expander is programmed during manufacturing to respond to a specific block of I/O port addresses. Only I/O ports with addresses in the range of a given bus expander may be connected to that expander. A bus expander may be used on either left bank or right bank. Multiple expanders on the same bank must have different address ranges; however, expanders with the same address range can be connected if they are on different banks. Systems may be configured with I/O ports connected directly to the 8X300, as well as I/O ports connected through a bus expander; however, no unbuffered I/O port may have an address within the span of a bus expander on the same bank.

Addition of bus expanders may impact system cycle time due to the added delay in the data path. For the purposes of calculating allowable cycle time as described in the 8X300 data sheet, the bus expander delays may be considered additive to the I/O port delays so that a buffered I/O port simply appears as a slower I/O port.

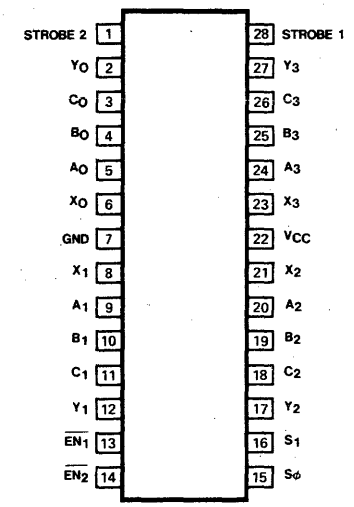
PRELIMINARY SPECIFICATION 8T40/29540 I,N

DESCRIPTION

The Pipelined I/O Port is designed as a high speed multiple input/multiple output latched bus transceiver. The unique two-latch/or multiple-bus organization is well suited for any application in which several data buses are interconnected.

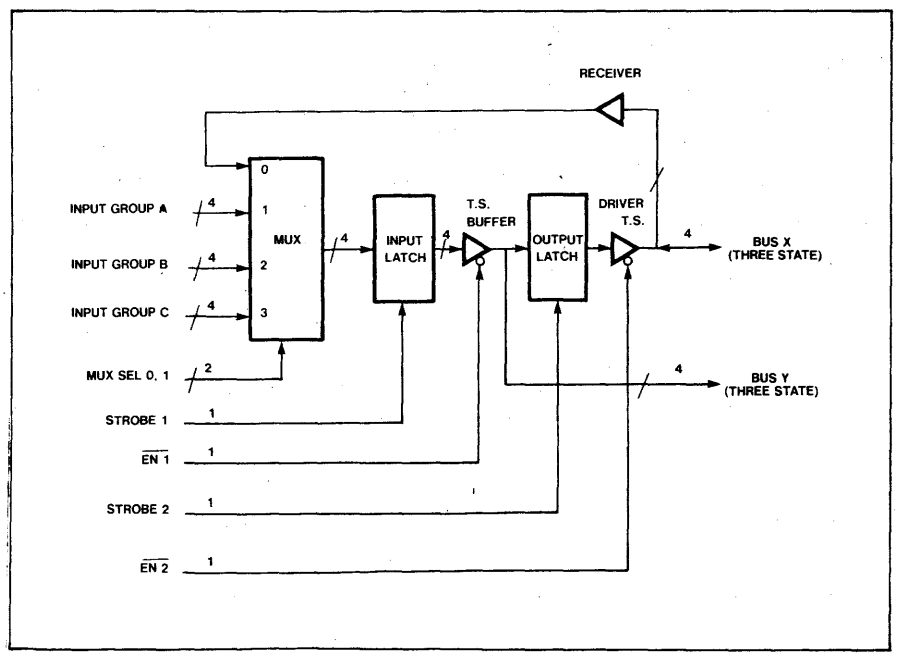
The organization of the part allows data from four sources (BUS X, INPUT A, INPUT B, INPUT C) to be routed to the INPUT LATCH. The INPUT LATCH drives bus Y via a three state 20mA driver. Bus Y can be driven by the INPUT LATCH via the three state Y bus driver, latched into the INPUT LATCH, or both. The OUTPUT LATCH is then able to drive Bus X via the Bus X three state 40mA driver, or Bus X can be latched into the input latch, or both. Use of the circuit is simplified by separate control lines to the INPUT MULTIPLEXER, INPUT LATCH, OUTPUT LATCH, and the three state drivers. Advanced low power Schottky processing is used to fabricate this 28 lead dual-in-line device.

FEATURES



- **4 Bit organization on all data paths**
- **2 Output buses with high current, three-state drivers**
- **2 Internal storage latches**
- **Organized for efficient interconnection to multiple buses**
- **4 Data paths to the input latch**
- **Separate input latch and output latch strobes**
- **Simple control, easy to use**
- **Low power Schottky technology**
- **28 Pin dual-in-line package**

APPLICATIONS



- **Data routing between floating point processor, CPU & Memory; or other sources**
- **Multiport memory data and address handling**
- **Data path element for CPU, I/O & memory**
- **Byte swap, character swap, without CPU intervention**
- **Ideal for the following system environments:**
  - **Bipolar Microcomputer Systems**
  - **Bipolar Minicomputer Systems**
  - **Data Communications**
  - **Smart Peripheral Controllers**
  - **Multiprocessing Systems**

8T58-I,XL

DESCRIPTION

The Bus Expander is specifically designed to increase the I/O capability of 8X300 systems previously limited by fanout considerations. The bus expander serves as a buffer between the 8X300 and blocks of I/O devices. Each bus expander can buffer a block of 16 I/O ports while only adding a single load to the 8X300.

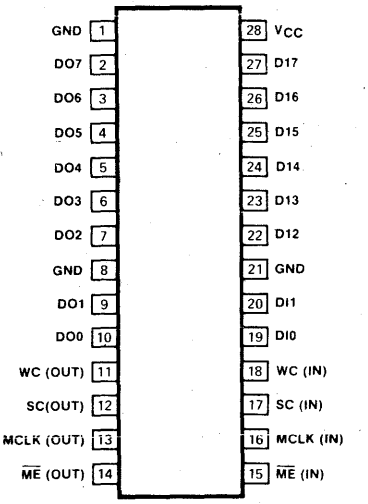
FEATURES

- **15ns max propagation delay**
- **Bidirectional**
- **Three-state outputs on both ports**

FUNCTIONAL DESCRIPTION

The Bus Expander contains eight sets of non-inverting bidirectional tri-state drivers for the bus data bits, four non-inverting undirectional drivers for I/O port control, and necessary control logic. The control logic is required to maintain the proper directional transfer of bus data as dictated by the states of the I/O port control signals. A bus expander may be used on either left bank or right bank. Systems may be configured with I/O ports connected directly to the 8X300, as well as I/O ports connected through a bus expander.

Addition of bus expanders may impact system cycle time due to the added delay in the data path. For the purposes of calculating allowable cycle time as described in the 8X300 data sheet, the bus expander delays may be considered additive to the I/O port delays so that a buffered I/O port simply appears as a slower I/O port.



APPLICATIONS

The 8T39 Bus Expander is designed to be used with the 8X300 microprocessor to allow increased I/O capability in those systems previously limited by fanout considerations. Figure 1 shows a typical arrangement of the bus expander in an 8X300 system. Other I/O ports or working storage may be directly connected to the bus as shown.

The bus expander is not limited to use with the 8X300, but may be applied in any system which uses a combined address/data bus.

DESCRIPTION

Each of the 3-State Bus Interface Elements described herein has low current PNP inputs and is designed with Schottky TTL technology for ultra high speed. The devices are used to convert TTL/DTL or MOS/CMOS to 3-state TTL Bus levels. For maximum systems flexibility the 8T95 and 8T97 do so without logic inversion, whereas, the 8T96 and 8T98 provide the logical complement of the input. The 8T95 and 8T96 feature a common control line for all six devices, whereas, the 8T97 and 8T98 have control lines for four devices from one input and two from another input.

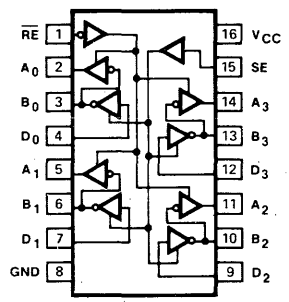
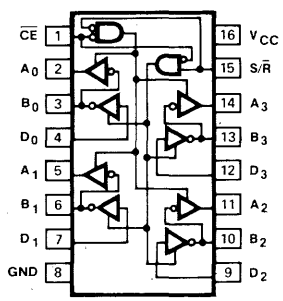
DESCRIPTION



The 8T126 thru 8T129 are quad transceivers designed to handle many bus interface applications. The devices feature 3-state outputs on both send and receive buffers, and pnp transistors on all inputs to reduced input LOW loading requirements.

The 8T126 and 8T128 feature a 3.4V minimum V_{OH} level on the receiver for MOS interface applications. The send and receive buffers have separate enable inputs for independent control.



The 8T127 and 8T129 feature full 24mA drive in both send and receive buffers. These devices have a common Chip Enable input for easy cascading, and a Send/Receive input for direction control.

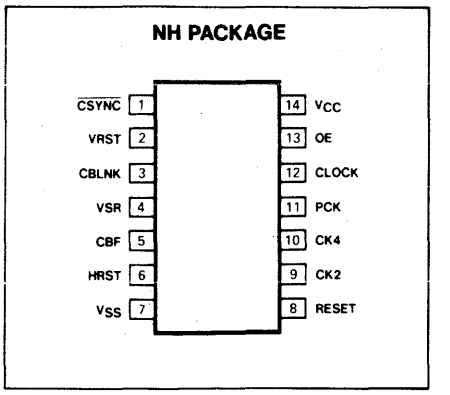
PRELIMINARY SPECIFICATION

DESCRIPTION

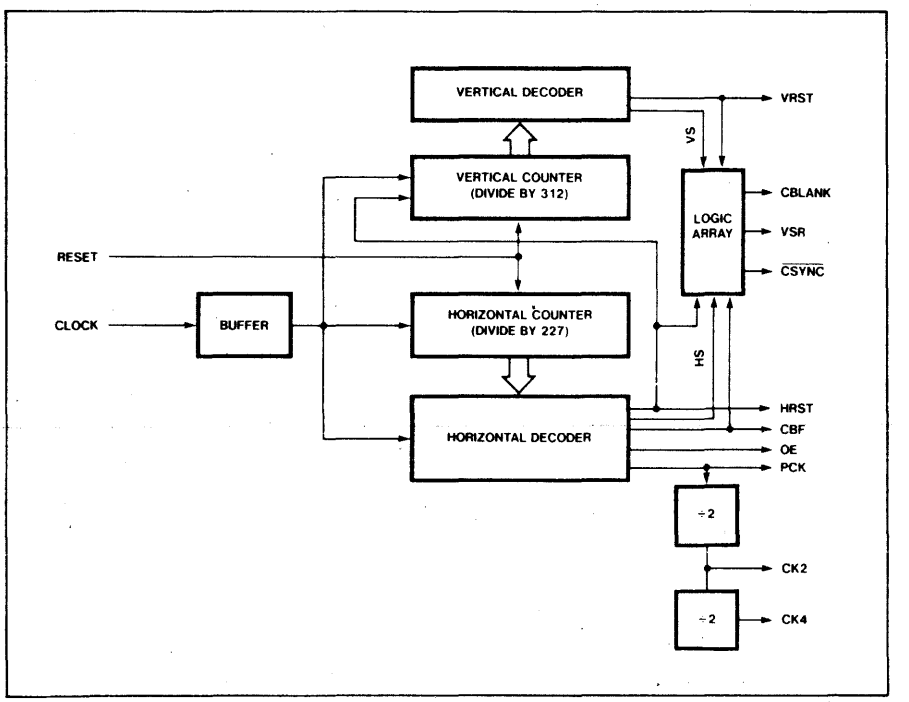
The Signetics 2621 Universal Sync Generator (USG) provides the timing and control signals necessary for generating and displaying TV video information in the PAL format.

The USG accepts a single 3.55MHz input clock and generates various timing outputs including vertical, horizontal and composite blanking, composite sync and color burst flag. Several auxiliary clock outputs are also provided.



The USG is primarily intended for use in microprocessor-controlled video games. A typical game configuration consists of a 2621 USG, a 2650A microprocessor, a 2636 Programmable Video Interface, a 2616 16K ROM, and digital video summer circuitry.

The 2621 is constructed using Signetics silicon gate N-channel depletion load technology and operates from a single +5 volt power supply.



The Signetics 2622 Universal Sync Generator (USG) provides the timing and control signals necessary for generating and displaying TV video information in the NTSC format.

The USG accepts a single 3.5795MHz input clock and generates various timing outputs including vertical, horizontal, and composite blanking, composite sync and color burst flag. Several auxiliary clock outputs are also provided. The USG is primarily intended for use in microprocessor-controlled video games. A typical game configuration consists of a 2622 USG, a 2650A microprocessor, a 2636 Programmable Video Interface, a 2616 16K ROM, and an NE549 Digital Video Summer. The 2622 is constructed using Signetics silicon gate N-channel depletion load technology and operates from a single +5 volt power supply.

PRELIMINARY SPECIFICATION 2636I

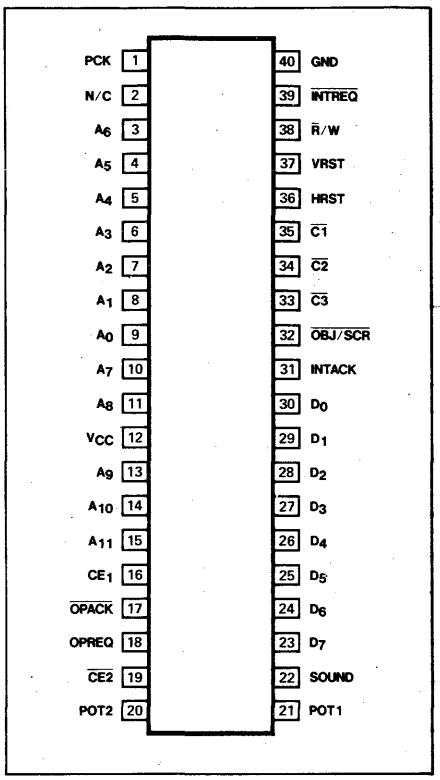
DESCRIPTION

The Signetics 2636 Programmable Video Interface (PVI) is intended for use in microprocessor-controlled game systems, and provides all of the common game circuits on a single chip. Circuits are provided for player inputs, background, moving objects, scoring, and audio signals.

A typical system configuration consists of five LSI circuits: a PVI, a 2616 16K ROM, an NE549 Digital Video Summer (DVS) a Universal Sync Generator (USG), and a 2650A microprocessor.

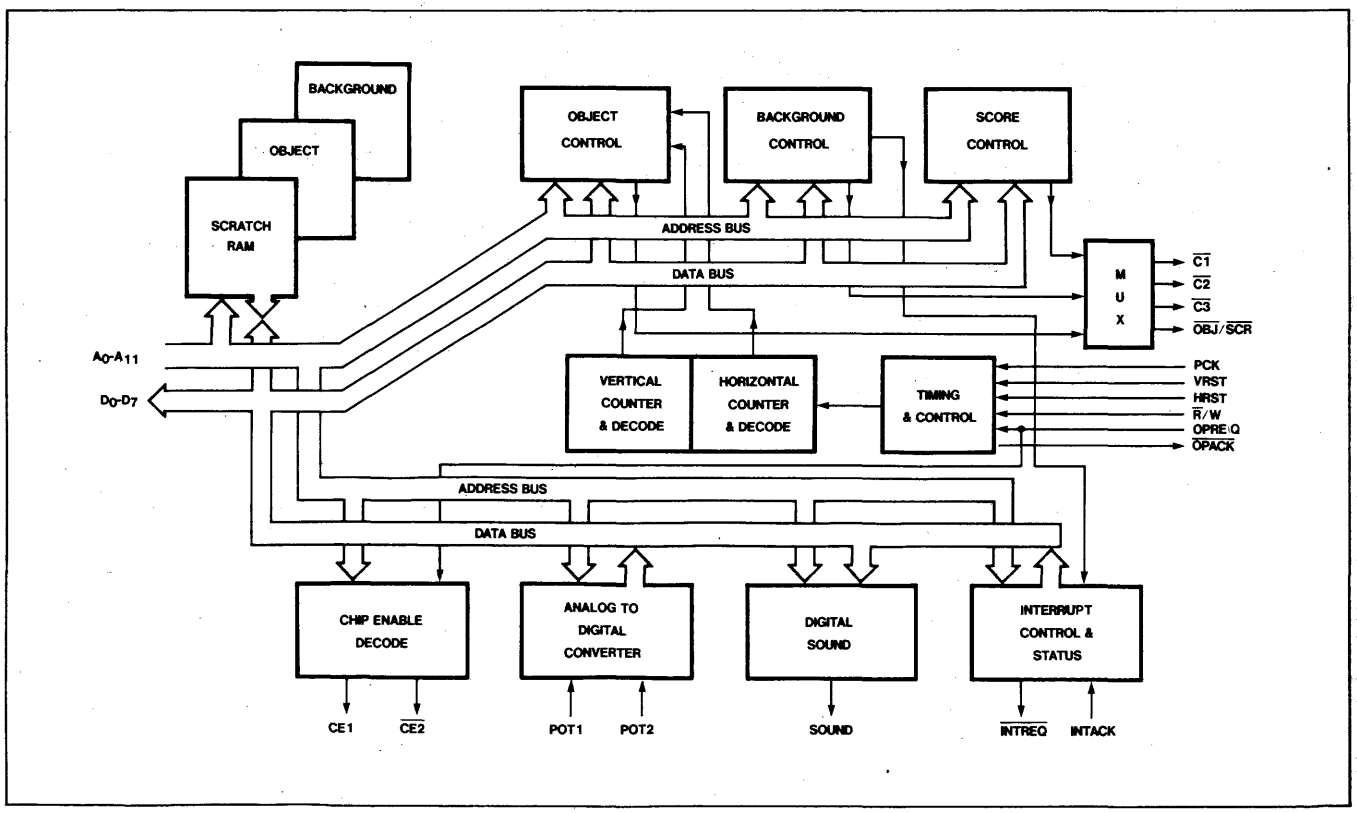
Additional PVIs as well as random logic can easily be interfaced to enhance game complexity. Since the system is microprocessor based, the actual game itself need not be "hardwired" into the system. Game definition is completely contained in the ROM. To change games, one simply replaces one ROM with another. Each ROM can contain several games, depending on game complexity and similarity between games.

The 2636 PVI is constructed using Signetics' silicon gate N-Channel depletion load technology and operates from a single +5 volt power supply.



FEATURES

- **Four general-purpose, RAM-resident object modules**
- **Object duplication permitting generation of up to 80 object images on the screen**
- **280ns object resolution**
- **Object size and position under program control**
- **Programmable score**
- **Programmable sound**
- **Programmable background**
- **Eight programmable colors with multiple brightness levels**
- **37-byte scratch pad memory**
- **Chip Enable outputs for system ROMs and PROMs**
- **I/O facilities for switch scanning and potentiometer inputs**
- **Wire-OR expansion capability to multiple PVIs**
- **Forty-pin dual-in-line package**



APPLICATIONS

- **Consumer programmable video games**
- **Arcade games**
- **Simulators**
- **Special purpose graphic displays**
- **Home computer center**

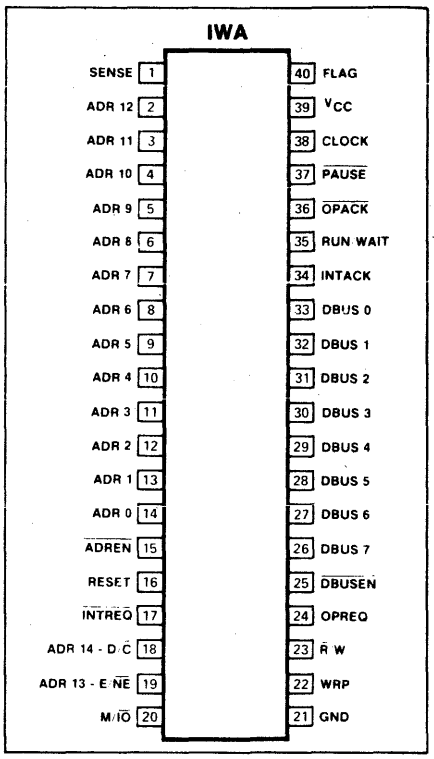
PRELIMINARY SPECIFICATION

DESCRIPTION

The 2650A and -1 are additional members of the Signetics family of 8 bit, NMOS microprocessors.



The 2650A is a functional equivalent of the 2650 with a new mask design which provides improved device operating margins.

The 2650A-1 is a high speed version of the 2650A.

FEATURES

- **Static 8 bit parallel NMOS microprocessor**
- **Single power supply of +5 volts**
- **TTL level single phase clock**
- **Standard 40 pin dual in-line package**
- **TTL compatible inputs and outputs**
- **75 variable length instructions of 1, 2 or 3 bytes**
- **32k byte address range**
- **Coding efficiency with multiple addressing modes**
- **Synchronous or asynchronous memory and I/O interface**
- **Interfaces directly with industry standard memories**
- **Single bit serial I/O path**
- **Seven 8 bit addressable general purpose registers**
- **Vectored interrupt**
- **Subroutine return address stack**
- **2.4μs machine cycle time (2650A)**
- **1.5μs machine cycle time (2650A-1)**

PRELIMINARY SPECIFICATION

FUNCTIONAL DESCRIPTION

The 2650 series processors are general purpose, single chip, fixed instruction set, parallel 8-bit binary processors. A general purpose processor can perform any data manipulations through execution of a stored sequence of machine instructions. The processor has been designed to closely resemble conventional binary computers, but executes variable length instructions of one to three bytes in length.

The 2650 series contains a total of seven general purpose registers, each eight bits long. They may be used as source or destination for arithmetic operations, as index registers, and for I/O transfers.

The processor can address up to 32,768 bytes of memory in four pages of 8,192 bytes each. The processor instructions are one, two, or three bytes long, depending on the instruction. Variable length instructions tend to conserve memory space since a one-or-two byte instruction may often be used rather than a three byte instruction. The first byte of each instruction always specifies the operation to be performed and the addressing mode to be used. Most instructions use six of the first eight bits for this purpose, with the remaining two bits forming the register field. Some instructions use the full eight bits as an operation code.

The Data Bus and Address signals are tristate to provide convenience in system design. Memory and I/O interface signals are asynchronous so that Direct Memory Access (DMA) and multiprocessor operations are easy to implement.

The block diagram for the 2650 series (Figure 1) shows the major internal components and the data paths that interconnect them. In order for the processor to execute an instruction, it performs the following general steps:

1. The Instruction Address Register provides an address for memory.
2. The first byte of an instruction is fetched from memory and stored in the Instruction Register.
3. The Instruction Register is decoded to determine the type of instruction and the addressing mode.
4. If an operand from memory is required, the operand address is resolved and loaded into the Operand Address Register.
5. The operand is fetched from memory and the operation is executed.
6. The first byte of the next instruction is fetched.

The Instruction Register (IR) holds the first byte of each instruction and directs the subsequent operations required to execute each instruction. The IR contents are decoded and used in conjunction with the timing information to control the activation and sequencing of all the other elements on the chip. The Holding Register is used in some multiple-byte instructions to contain further instruction information and partial absolute addresses.

The Arithmetic Logic Unit (ALU) is used to perform all of the data manipulation operations, including Load, Store, Add, Subtract, And, Inclusive Or, Exclusive Or, Compare, Rotate, Increment and Decrement. It contains and controls the Carry bit, the Overflow bit, the Interdigit Carry and the Condition Code Register.

The Register Stack contains six registers that are organized into two banks of three registers each. The Register Select bit picks one of the two banks to be accessed by instructions. In order to accommodate the register-to register instructions, register zero (R0) is outside the array. Thus, register zero is always available along with one set of three registers.

The Address Adder is used to increment the instruction address and to calculate relative and indexed addresses.

The Instruction Address Register holds the address of the next instruction byte to be accessed. The Operand Address Register stores operand addresses and sometimes contains intermediate results during effective address calculations.

The Return Address Stack (RAS) is a Last In, First Out (LIFO) storage which receives the return address whenever a Branch-to-Subroutine instruction is executed. When a Return instruction is executed, the RAS provides the last return address for the processor's IAR. The stack contains eight levels of storage so that subroutines may be nested up to eight levels deep. The Stack Pointer is a three bit wraparound counter that indicates the next available level in the stack. It always points to the current address.

PROGRAM STATUS WORD

The Program Status Word (PSW) is a major feature of the 2650 which greatly increases its flexibility and processing power. The PSW is a special purpose register within the processor that contains status and control bits.

It is divided into two bytes called the Program Status Upper (PSU) and Program Status Lower (PSL). The PSW bits may be tested, loaded, stored, preset, or cleared using the instructions which affect the PSW. The bits are utilized as shown in Table 1.

PSU0,1,2	SP	Pointer for the Return Address Stack.
PSU3,4		Not used. These bits are always zero.
PSU5	II	Used to inhibit recognition of additional Interrupts.
PSU6	F	Flag is a latch directly driving the flag output.
PSU7	S	Sense equals the state of the sense input.
PSL0	C	Carry stores any carry from the high-order bit of ALU.
PSL1	COM	Compare determines if a logical or arithmetic comparison is to be made.
PSL2	OVF	Overflow is set if a two's complement overflow occurs.
PSL3	WC	With Carry determines if the carry is used in arithmetic and rotate instructions.
PSL4	RS	Register Select identifies which bank of 3 GP registers is being used.
PSL5	IDC	Inter Digit Carry stores the bit-3 to-bit-4 carry in arithmetic operations.
PSL6,7	CC	Condition Code is affected by compare, test and arithmetic instructions.

2651-I

DESCRIPTION

The Signetics 2651 PCI is a universal synchronous/asychronous data communications controller chip designed for microcomputer systems. It interfaces directly to the Signetics 2650 microprocessor and may be used in a polled or interrupt driven system environment. The 2651 accepts programmed instructions from the microprocessor and supports many serial data communication disciplines, synchronous and asynchronous, in the full or half-duplex mode.

The PCI serializes parallel data characters received from the microprocessor for transmission. Simultaneously, it can receive serial data and convert it into parallel data characters for input to the microcomputer.

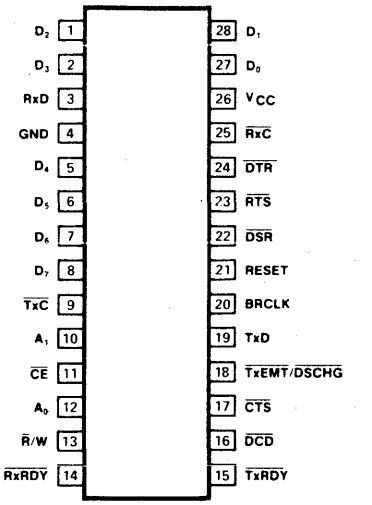
The 2651 contains a baud rate generator which can be programmed to either accept an external clock or to generate internal transmit or receive clocks. Sixteen different baud rates can be selected under program control when operating in the internal clock mode.

The PCI is constructed using Signetics n-channel silicon gate depletion load technology and is packaged in a 28-pin DIP.

FEATURES

- **Synchronous operation**
  - **5 to 8-bit characters**
  - **Single or double SYN operation**
  - **Internal character synchronization**
  - **Transparent or non-transparent mode**
  - **Automatic SYN or DLE-SYN insertion**
  - **SYN or DLE stripping**
  - **Odd, even, or no parity**
  - **Local or remote maintenance loop back mode**
  - **Baud rate: dc to 1M bps (1X clock)**
- **Asynchronous operation**
  - **5 to 8-bit characters**
  - **1, 1 1/2 or 2 stop bits**
  - **Odd, even, or no parity**
  - **Parity, overrun and framing error detection**
  - **Line break detection and generation**
  - **False start bit detection**
  - **Automatic serial echo mode**
  - **Local or remote maintenance loop back mode**
  - **Baud rate: dc to 1M bps (1X clock)**
    - **dc to 62.5K bps (16X clock)**
    - **dc to 15.625K bps (64X clock)**

OTHER FEATURES



- **Internal or external baud rate clock**
- **16 internal rates-50 to 19,200 baud**
- **Double buffered transmitter and receiver**
- **Full or half duplex operation**
- **Fully compatible with 2650 CPU**
- **TTL compatible inputs and outputs**
- **Single 5V power supply**
- **No system clock required**
- **28-pin dual in-line package**

APPLICATIONS

- **Intelligent terminals**
- **Network processors**
- **Front end processors**
- **Remote data concentrators**
- **Computer to computer links**
- **Serial peripherals**

BLOCK DIAGRAM

BLOCK DIAGRAM

The PCI consists of six major sections. These are the transmitter, receiver, timing, operation control, modem control and SYN/DLE control. These sections communicate with each other via an internal data bus and an internal control bus. The internal data bus interfaces to the microprocessor data bus via a data bus buffer.

Operation Control

This functional block stores configuration and operation commands from the CPU and generates appropriate signals to various internal sections to control the overall device operation. It contains read and write circuits to permit communications with the microprocessor via the data bus and contains Mode Registers 1 and 2, the Command Register, and the Status Register. Details of register addressing and protocol are presented in the PCI Programming section of this data sheet.

Timing

The PCI contains a Baud Rate Generator (BRG) which is programmable to accept external transmit or receive clocks or to divide an external clock to perform data communications. The unit can generate 16 commonly used baud rates, any one of which can be selected for full duplex operation. See Table 1.

Receiver

The Receiver accepts serial data on the RxD pin, converts this serial input to parallel format, checks for bits or characters that are unique to the communication technique and sends an "assembled" character to the CPU.

Transmitter

The Transmitter accepts parallel data from the CPU, converts it to a serial bit stream, inserts the appropriate characters or bits (based on the communication technique) and outputs a composite serial stream of data on the TxD output pin.

Modem Control

The modem control section provides interfacing for three input signals and three output signals used for "handshaking" and status indication between the CPU and a modem.

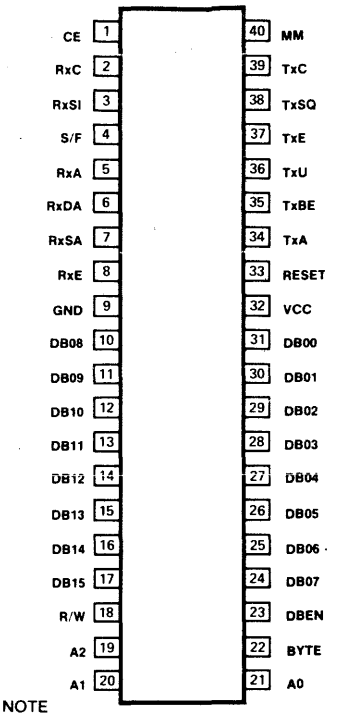
SYN/DLE Control

This section contains control circuitry and three 8-bit registers storing the SYN1, SYN2, and DLE characters provided by the CPU. These registers are used in the synchronous mode of operation to provide the characters required for synchronization, idle fill and data transparency.

DESCRIPTION

The 2652 Multi-Protocol Communications Controller (MPCC) is a monolithic n-channel MOS LSI circuit that formats, transmits and receives synchronous serial data while supporting bit-oriented or byte control protocols. The chip is TTL compatible, operates from a single +5V supply, and can interface to a processor with an 8 or 16-bit bidirectional data bus.

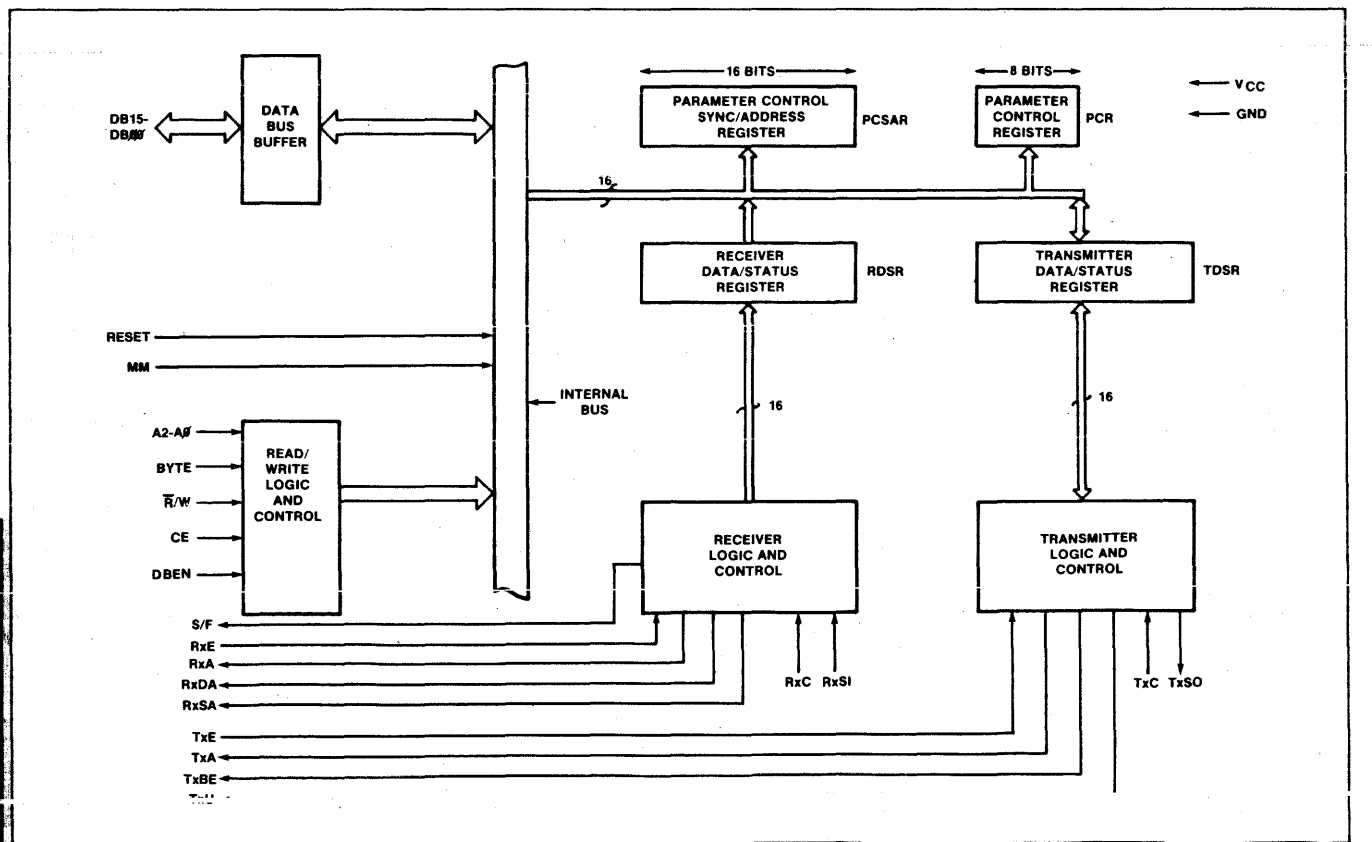
FEATURES



- DC to 1Mbps data rate, 2652-1 to 2Mbps
- Protocol management
  Bit-oriented protocols (BOP): SDLC, ADCCP, HDLC
  Byte-control protocols (BCP): BI-SYNC, DDCMP, limited BISYNC
- Programmable operation
  8 or 16-bit tri-state data bus
  Protocol selection—BOP or BCP
  Error control—CRC or VRC or no error check
  Character length—1 to 8 bits for BOP or 5 to 8 bits for BCP
  SYNC or secondary station address comparison for BCP-BOP
  Idle transmission of SYNC/FLAG or MARK for BCP-BOP
- Automatic detection and generation of special BOP control sequences, i.e., FLAG, ABORT, GA
- Zero insertion and deletion for BOP
- Short character detection for last BOP data character (will not overrun)
- SYNC generation, detection, and stripping for BCP
- Maintenance Mode for self-testing
- Common parameter control registers
- Independent status and data registers for receive and transmit
- Status indicator signals can be used as CPU interrupts
- TTL compatible
- 40-pin package
- Single +5V supply

APPLICATIONS

- Intelligent terminals
- Line controllers
- Network processors
- Front end communications
- Remote data concentrators
- Communication test equipment
- Computer to computer links



PIN CONFIGURATION

IWA PACKAGE

NOTE
00 is least significant bit, highest number (that is, DB15, A2) is most significant bit.

BLOCK DIAGRAM

©IC MASTER 1979

PIN DESIGNATION

MNEMONIC	PIN NO.	TYPE	NAME AND FUNCTION
DB15-DB00	17-10 24-31	I/O	**Data Bus:** DB07-DB00 contain bidirectional data while DB15-DB08 contain control and status information to or from the processor. Corresponding bits of the high and low order bytes can be WIRE OR'ed onto an 8-bit data bus.
A2-A0	19-21	I	**Address Bus:** A2-A0 select internal registers. The four 16-bit registers can be addressed on a word or byte basis. See Register Address section.
BYTE	22	I	**Byte:** Single byte (8 bit) data bus transfers are specified when this input is high. A low level specifies 16 bit data bus transfers.
CE	1	I	**Chip Enable:** A high input permits a data bus operation when DBEN is activated.
$\overline{R}$/W	18	I	**Read/Write:** $\overline{R}$/W controls the direction of data bus transfer. When high, the data is to be loaded into the addressed register. A low input causes the contents of the addressed register to be presented on the data bus.
DBEN	23	I	**Data Bus Enable:** After A2-A0, CE, BYTE and $\overline{R}$/W are set up, DBEN may be strobed. During a read, the tri-state data bus (DB) is enabled with information for the processor. During a write, the stable data is loaded into the addressed register and TxBE will be reset if TDSR was addressed.
RESET	33	I	**Reset:** A high level initializes all internal registers (to zero) and timing.
MM	40	I	**Maintenance Mode:** MM internally gates TxSO back to RxSI and $\overline{TxC}$ to RxC for off line diagnostic purposes. The RxC input is disabled when MM is asserted.
RxE	8	I	**Receiver Enable:** A high level input permits the processing of RxSI data. A low level disables the receiver logic and initializes all receiver registers and timing.
RxA	5	O	**Receiver Active:** RxA is asserted when the first data character of a message is ready for the processor. In the BOP mode this character is the address. The received address must match the secondary station address if the MPCC is a secondary station. In BCP mode, if strip-SYNC ($PCSAR_{13}$) is set, the first non-SYNC character is the first data character; if strip-SYNC is zero, the character following the second SYNC is the first data character. In the BOP mode, the closing FLAG resets RxA. In the BCP mode, RxA is reset by a low level at RxE.
RxDA*	6	O	**Receiver Data Available:** RxDA is asserted when an assembled character is in $RDSR_L$ and is ready to be presented to the processor. This output is reset when $RDSR_L$ is read.
RxC	2	I	**Receiver Clock:** RxC(1X) provides timing for the receiver logic. The positive going edge shifts serial data into the RxSR from RxSI.
S/F	4	O	**SYNC/FLAG:** S/F is asserted for one RxC clock time when a SYNC or FLAG character is detected.
RxSA*	7	O	**Receiver Status Available:** RxSA is asserted when there is a zero to one transition of any bit in $RDSR_H$ except for RSOM. It is cleared when $RDSR_H$ is read.
RxSI	3	I	**Receiver Serial Input:** RxSI is the received serial data. Mark = '1', space = '0'.
TxE	37	I	**Transmitter Enable:** A high level input enables the transmitter data path between $TDSR_L$ and TxSO. At the end of a message, a low level input causes TxSO = 1 (mark) and TxA = 0 after the closing FLAG (BOP) or last character (BCP) is output on TxSO.
TxA	34	O	**Transmitter Active:** TxA is asserted when TxE is high and TSOM ($TDSR_8$) is set. This output will reset when TxE is low and the closing FLAG (BOP) or last character (BCP) has been output on TxSO.
TxBE*	35	O	**Transmitter Buffer Empty:** TxBE is asserted when the TDSR is ready to be loaded with new control information or data. The processor should respond by loading the TDSR which resets TxBE.
TxU*	36	O	**Transmitter Underrun:** TxU is asserted during a transmit sequence when the service of TxBE has been delayed for one character time. This indicates the processor is not keeping up with the transmitter. Line fill depends on $PCSAR_{11}$. TxU is reset by RESET or setting of TSOM ($TDSR_8$). ($TDSR_8$).
TxC	39	I	**Transmitter Clock:** TxC (1X) provides timing for the transmitter logic. The positive going edge shifts data out of the TxSR to TxSO.
TxSO	38	O	**Transmitter Serial Output.** TxSO is the transmitted serial data. Mark = '1', space = '0'.
V_{CC}	32	I	**+5V:** Power supply.
GND	9	I	**Ground:** 0V reference ground.

*Indicates possible interrupt signal.

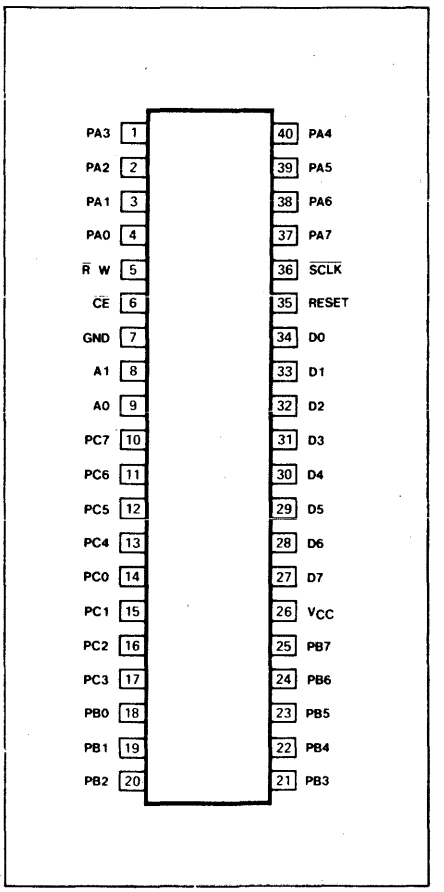
DESCRIPTION

The 2655 Programmable Peripheral Interface (PPI) is a general purpose I/O component designed for microcomputer systems. It consists of three ports (24 I/O pins) which can be individually programmed to function as input, output or bidirectional ports. Interface with a microprocessor is via an 8-bit bidirectional data bus. Although designed primarily for use in 2650-based microcomputer systems, the 2655 can be easily interfaced to other microprocessors.



The PPI ports can be programmed to operate in one or more of seven operational modes: Static I/O, Strobed Input, Strobed Output, Strobed Bidirectional, Serial Input, Serial Output and Timer. The 2655 is fabricated using N-channel silicon gate technology and is packaged in a 40-pin DIP.

PIN DESIGNATION

PIN NO.	MNEMONIC	TYPE	NAME & FUNCTION
27-34	D7-D0	I/O	**Data Bus:** 8-bit 3-state, bidirectional data bus used for all data and command transfers.
35	RESET	I	**RESET:** When high, clears all internal registers. Clears Port A, B and C latches to zero and sets operating mode to Static I/O mode. An automatic power-on reset circuit is also provided.
8,9	A1,A0	I	**Address Bus:** A1, A0 select internal PPI registers. Select control or data words to be placed on the data bus. Used in conjunction with $\overline{R}$/W line.
5	$\overline{R}$/W	I	**Read/Write:** When low, gates the selected register to the data bus. When high, gates the contents of the data bus into the selected register. An address line may be used for this function if the CPU used does not provide a $\overline{R}$/W output.
6	$\overline{CE}$	I	**Chip Enable:** When low, indicates that control and data lines to the PPI are valid. Used as the timing signal for read/write operations.
36	$\overline{SCLK}$	I	**Serial Clock:** Provides a clock for the parallel to serial or serial to parallel conversion modes.
37-40 1-4	PA7-PA0	I/O	**Port A:** An 8-bit 3-stateable omni-port.*
25-18	PB7-PB0	I/O	**Port B:** An 8-bit omni-port which has serial I/O capability. Serial data is double buffered. Port B also contains a 16-bit binary timer, which can operate simultaneously with the serial I/O capability.
10-13 17-14	PC7-PC0	I/O	**Port C:** An 8-bit omni-port. Port C bits are also used as control and status signals for Ports A and B.
26	V_{CC}	I	**Power Supply:** +5V
7	GND	I	**Ground:**

*NOTE
See Omni-Port description is static I/O mode description.

PIN CONFIGURATION

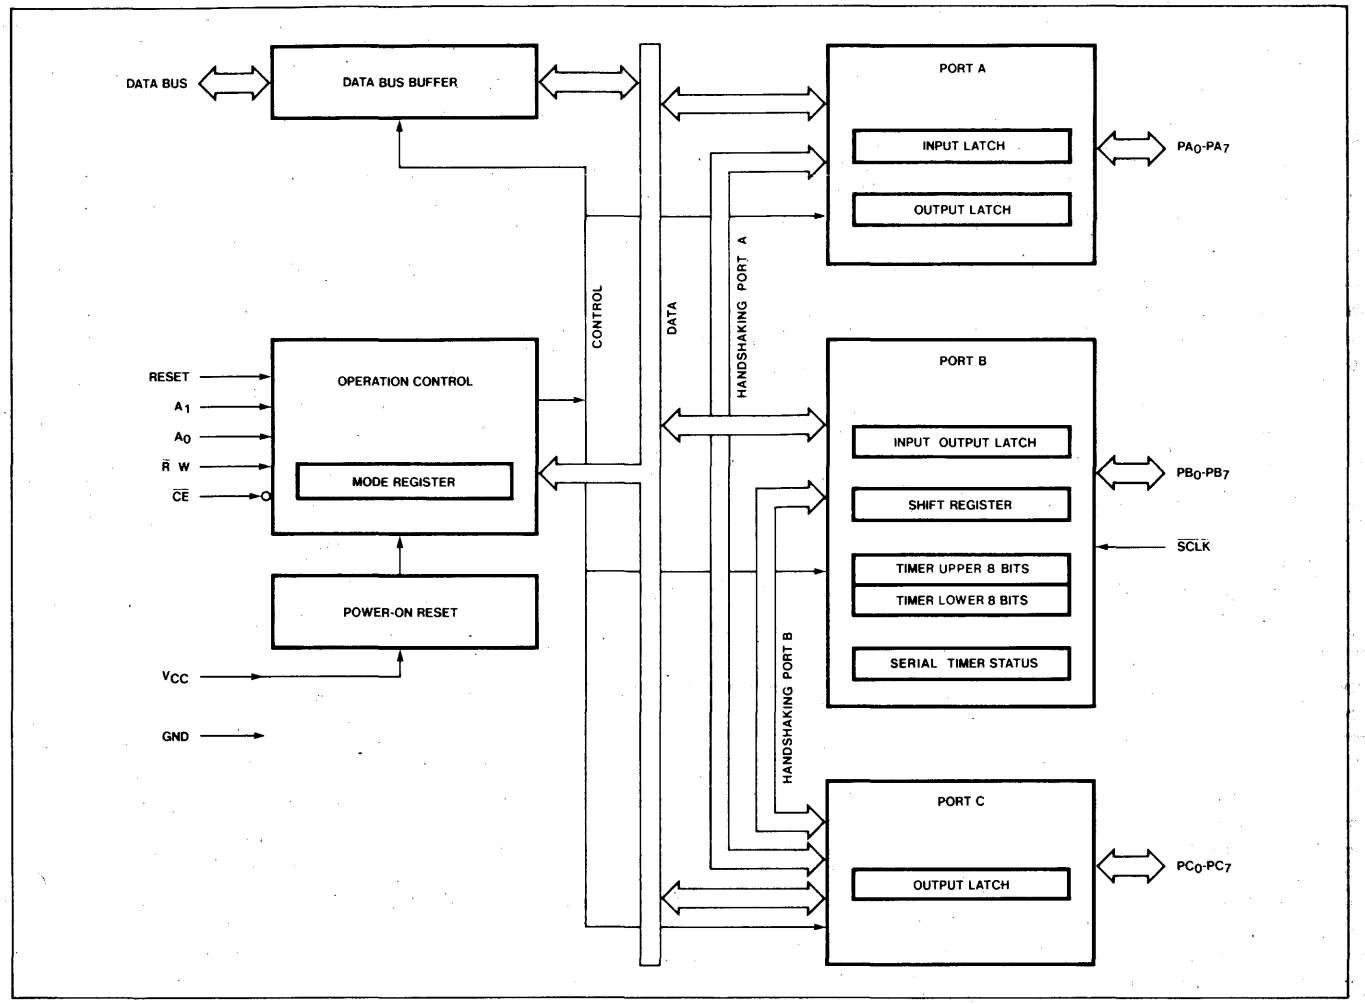
FEATURES

- **Seven selectable operating modes**
- **Three ports with 24 programmable I/O pins**
- **Completely TTL compatible**
- **Three MHz programmable timer or event counter**
- **Direct bit set reset capability**
- **300 ns port read/write access time**

FUNCTIONAL DESCRIPTION

The block diagram illustrates the major internal components of the PPI.

Data Bus Buffer



Three-state, bidirectional 8-bit buffer. All command and data transfers between the PPI and the CPU are accomplished via this buffer.

Operation Control

Access to the PPI is controlled by chip enable ($\overline{CE}$) and access to the various ports and registers is selected by address lines A0 and A1. The read/write ($\overline{R}$/W) signal selects the direction of the data flow between the PPI and the CPU. Table 1 specifies the inputs required to access the various internal registers.

©IC MASTER 1979

BLOCK DIAGRAM

The modes of operation of the PPI ports are selected by a control byte stored in the mode register. See the Mode Selection section of this specification.

Ports A, B and C

The 2655 contains three 8-bit ports, each of which may be configured to operate in a variety of data transfer modes by the system software.

PORT A: contains one 8-bit data output latch and one 8-bit data input latch. The port operates in either static I/O, strobed input, strobed output, or bidirectional I/O Mode.

PORT B: contains one 8-bit data input/output latch, one 8-bit shift register, one 16-bit binary counter (timer upper and lower 8 bits) and a serial/timer status register. The port operates in either static I/O, strobed input, strobed output, serial input, serial output, or timer mode. The timer mode may operate in conjunction with one of the serial modes.

PORT C: contains one 8-bit data output latch. The port operates in static I/O mode only. Port C bits are also used as control and status bits for ports A and B in certain modes of operation. A data selector selects the appropriate internal data path for the purpose of providing handshaking signals to and from Port C pins when used as control or status bits.

$\overline{CE}$	A1	A0	$\overline{R}/W$	FUNCTION
0	0	0	0	Read port A register
0	0	0	1	Write port A register
0	0	1	0	Read port B register
0	0	1	1	Write port B register
0	1	0	0	Read port C register
0	1	0	1	Write port C register
0	1	1	0	Read serial/timer status
0	1	1	1	Write mode register or bit set/reset
1	X	X	X	Data bus 3-state

PRELIMINARY SPECIFICATION

8048 8-BIT MICROCOMPUTER With Mask Programmable ROM
8748 8-BIT MICROCOMPUTER With Field Programmable Erasable EPROM
8035L 8-BIT MICROCOMPUTER With External ROM or PROM

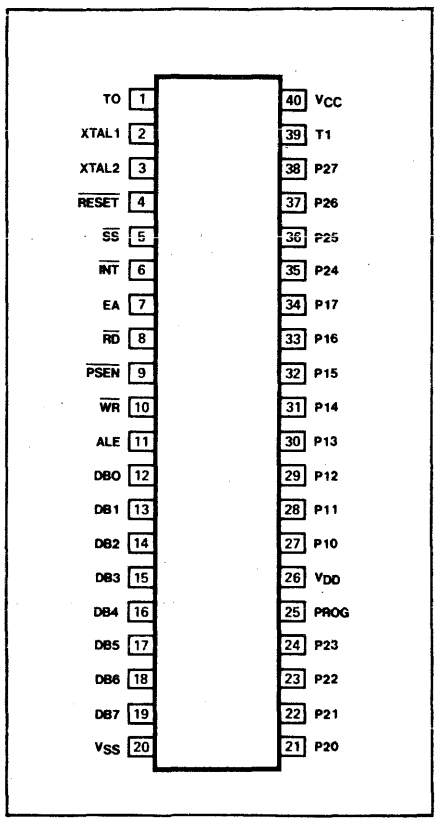
DESCRIPTION

The 8048 family of single chip 8-bit microcomputers are fabricated using the Signetics NMOS silicon gate process.

To reduce development and production costs and yet provide maximum flexibility, three interchangeable (pin compatible) versions of this single chip microcomputer are available:

- The 8748 with user-programmable and erasable EPROM, for prototype and pre-production systems.
- The 8048 with factory-programmable mask ROM for low-cost, high-volume production.
- The 8035L without program memory for use with external EPROM/ROM.

The 8048 family processors are designed to be efficient control processors as well as arithmetic processors. They provide an instruction set which allows the user to directly set and reset individual lines within its I/O ports as well as test individual bits within the accumulator. A large variety of branch and table look-up instructions make these processors very efficient in implementing standard logic functions. Also, special attention has been given to code efficiency. Over 70% of the instructions are a single byte long and all others are only two bytes long. This means many functions requiring 1.5K to 2.0K bytes in other computers may very well be compressed into the 1K words resident in the 8048.



An on-chip 8-bit counter is provided, which can, under program control, count either internal clock pulses (÷32) or external events. The counter can be programmed to cause an interrupt to be applied to the microcomputer.

Program and data memories can be expanded using low-cost, readily available, standard devices. Input/output capabilities can be expanded using standard devices or the 8243 I/O Expander of the 8048 family.

FEATURES

- **8-bit CPU, ROM, RAM, I/O in single package**
- **Interchangeable ROM/EPROM versions**
- **1Kx8 ROM/EPROM, 64x8 RAM, 27 I/O lines**
- **Internal counter/timer**
- **Internal oscillator, clock driver**
- **Single level interrupt: External or counter/timer**
- **17 internal registers: accumulator plus 16 addressable registers**
- **Over 90 instructions: 70% single byte**
- **All instructions: 1 or 2 cycles 2.5/5.0μs per cycle**
- **Easily exandable memory and I/O**
- **TTL compatible inputs and outputs**
- **Single 5V supply**
- **For low cost 28-Pin version see 8021 data sheet**

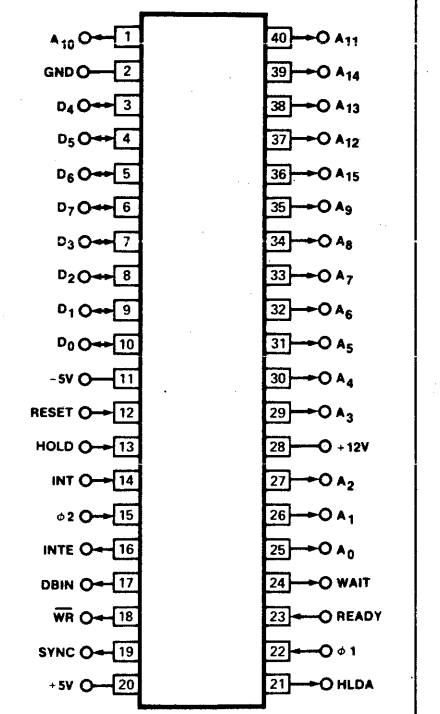
MP8080A-I

DESCRIPTION

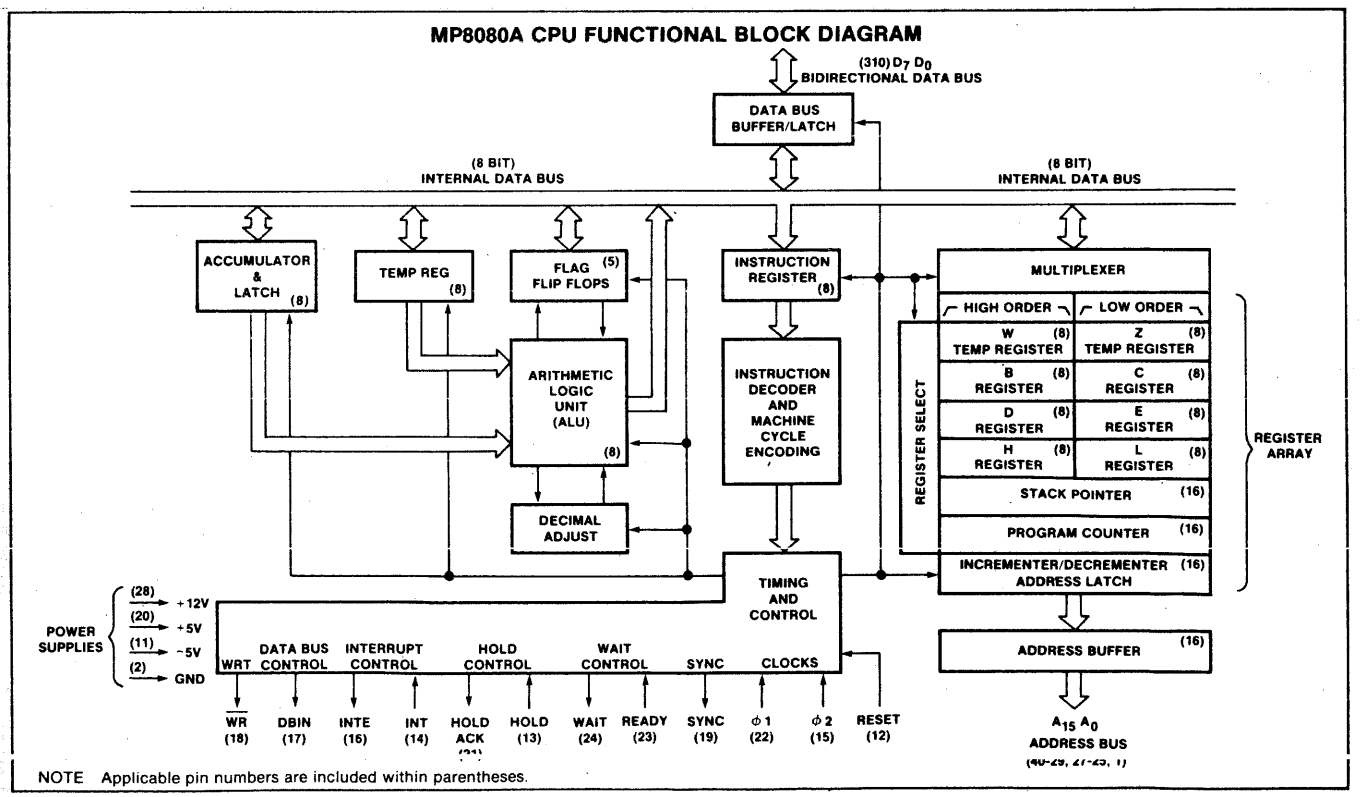
The MP8080A is an 8-bit microprocessor housed in a standard, 40-pin dual-in-line package. The chip, which is fabricated using N-channel silicon gate MOS technology, functions as the central processing unit (CPU) in Signetics' 8080 microcomputer family.

The MP8080A has a 16-bit address bus that is capable of addressing up to 65k bytes of memory and up to 256 input and 256 output devices. Data is routed to and from the MP8080A on a separate bidirectional 8-bit bus. This data bus is also Tri-State, making direct memory addressing (DMA) and multiprocessing applications possible. The MP8080A directly provides signals to control the interface to memory and I/O ports. All buses, including control, are TTL compatible.



An asynchronous interrupt capability is included in the MP8080A to allow external signals to change the instruction sequence. The interrupting device may vector the program to a particular service routine location (or some other direct function) by specifying an interrupt instruction to be executed.

FEATURES



- **2μs instruction cycle**
- **Variable length instructions**
- **General purpose registers—six plus an accumulator**
- **Direct addressing up to 65k bytes**
- **Variable length stack accessed by 16-bit stack pointer**
- **Addresses 256 input and 256 output ports**
- **Provisions for vectored interrupts**
- **Tri-state bus for DMA and multiprocessing capability**
- **Tri-state TTL drive capabilities for address and data buses**
- **Decimal arithmetic capability**
- **Multiple addressing modes**
  - **Direct**
  - **Register**
  - **Register indirect**
  - **Immediate**
- **Direct plug-in replacement for Intel MP8080A**

PIN CONFIGURATION

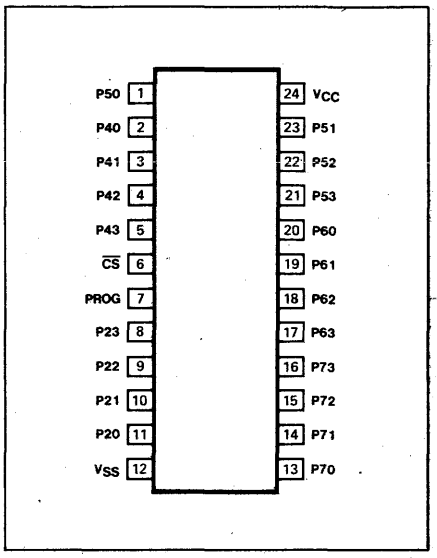
PRELIMINARY SPECIFICATION

DESCRIPTION



The 8243 is an input/output expander that provides an easy, low cost method of adding four 4-bit bidirectional, latched ports to 8048 and 8021 microcomputer based systems. Fabricated using the Signetics NMOS process, it features versatility, operation from a single 5 volt supply, and high current drive capability.

The data interface between the 8243 and the microcomputer is via the lower four bits of Port 2. Control is provided automatically by the PROG line when the MOVD P,A, MOVD A,P, ANLD P,A, or ORLD P,A instructions are executed.

FEATURES

- **Low cost**
- **Single 5V supply**
- **High output current drive**
- **Direct interface to 8048 and 8021 family of microcomputers**
- **Four 4-bit I/O ports**
- **Chip Select input for easy expansion**

ISP-8A/600-I

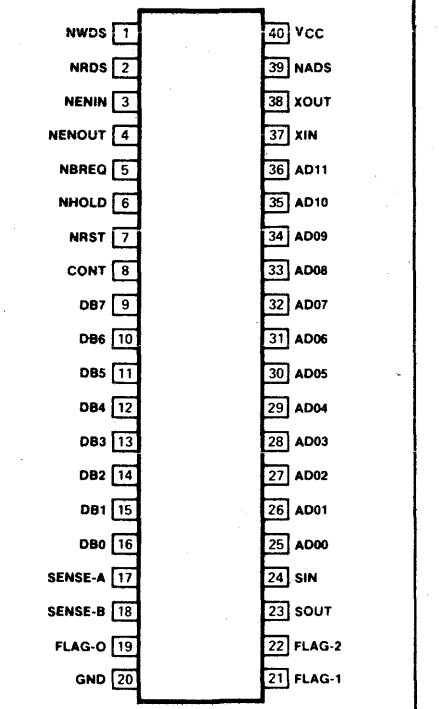
DESCRIPTION

SC/MP (Simple Cost-effective MicroProcessor) is a single-chip 8-bit microprocessor packaged in a standard, 40-pin, dual-in-line package.

N-channel, silicon gate, depletion mode standard-process technology ensures high performance, high reliability, and high producibility.

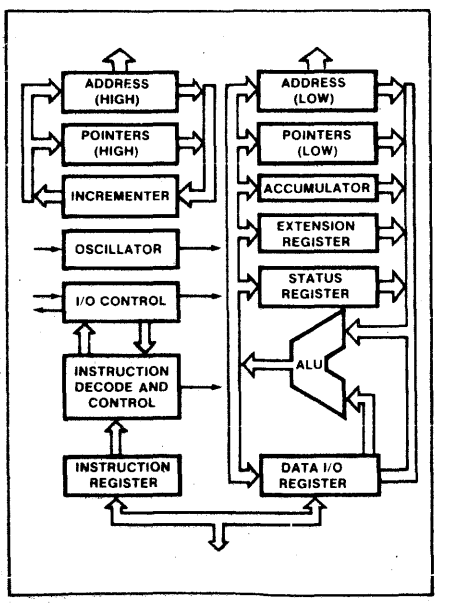
SC/MP is intended for use in general-purpose applications where cost per function is a most significant criterion. But cost efficiency is only a part of SC/MP's story. It goes on to include a variety of useful functions that are not even provided by some of the expensive microprocessors, like self-contained timing circuitry, 16-bit (65K) addressing capability, serial or parallel data-transfer capability and common memory/peripheral instructions. The built-in features in conjunction with the low initial cost describe what SC/MP really is—a microprocessor specifically designed to provide the simplest and most efficient solution to many application requirements.

APPLICATIONS



- **Test systems and instrumentation**
- **Machine tool control**
- **Small business machines**
- **Word processing systems**
- **Educational systems**
- **Multiprocessor systems**
- **Process controllers**
- **Terminals**
- **Traffic controls**
- **Laboratory controllers**
- **Sophisticated games**
- **Automotive**

FEATURES



- **Simpler interfacing**
  - **Bidirectional Tri-state 8-bit data bus**
  - **TTL-compatible input/output interface**
- **Si-gate N-channel ion-implant process**
- **Direct Memory Access (DMA) and multiprocessor capabilities**
  - **Handshake bus-access control on chip**
- **Simplified programming**
  - **Multiple addressing modes—program-counter-relative, immediate data, indexed, auto-indexed, and implied**
- **Direct control output**
  - **Three user-accessible control-flag outputs**
- **Simpler I/O hardware**
  - **Separate serial-data input and output ports**
  - **Two sense inputs**
  - **Direct interfacing to standard memory parts**
- **Simplified timing hardware**
  - **On-chip clock generator**
- **Interface flexibility**
  - **Capability to interface with memories or peripherals of any speed**
- **Large system capability**
  - **Address capability to 65K bytes of memory**
- **Simplified power requirements**
  - **Single 5-volt supply**
  - **Low power**

PIN CONFIGURATION

DESCRIPTION

The TWIN (TestWare Instrument) system, shown in the block diagram of Figure 1, consists of interdependent subsystems, each contributing to the total task of implementing user microprocessor applications from initial concept to actual hardware operation. The system closely resembles a general-purpose minicomputer during the initial stages of product development, and allows source programs to be entered, edited and assembled into object programs. Object programs may be executed simply as programs, or as part of a user's product emulation. When programs have been run and debugged to the user's satisfaction, the TWIN system is capable of programming PROM devices for inclusion in the user's prototype hardware.

The program development computer is configured using plug-in modules, each dedicated to a specific task within the system. Each module interacts with the others by use of a common bus structure. The major buses include a data bus, an address bus, and a control bus. The program development computer acts as the controller for the entire system, and performs the necessary functions of transferring data to and from system peripherals.

To facilitate system operation, a dual-drive floppy disk subsystem is provided in all TWIN configurations. This subsystem, with integral controller, stores user program "files" and allows retrieval of these files for operations by the editor and assembler. The Signetics Disk Operating System (SDOS) software is loaded from the disk system into the development computer. SDOS provides complete control over all portions of the TWIN system.

A CRT console is the standard device for entering user programs. It is equipped with a full ASCII keyboard for data entry and a CRT display to allow the operator to view the results of his program manipulations during editing, assembly, and debug operations. The display and keyboard can be separated for user convenience. An interface is provided for an ASR-33 teletypewriter, which can be used in place of the CRT console. An optional line printer provides hard copy output.

Other system I/O devices can be added to the system to enhance its capabilities. Physical interface to the system bus is accomplished by use of the optional General-Purpose I/O card. Addition of a peripheral device requires addition of its software driver to the TWIN operating system.

TWICE (TestWare In-Circuit Emulation) denotes hardware/software elements of the TWIN system that support the integration and check-out of the user's prototype product. A number of different TWICE operation modes support product development, integration, and production.

THE TWIN SYSTEM

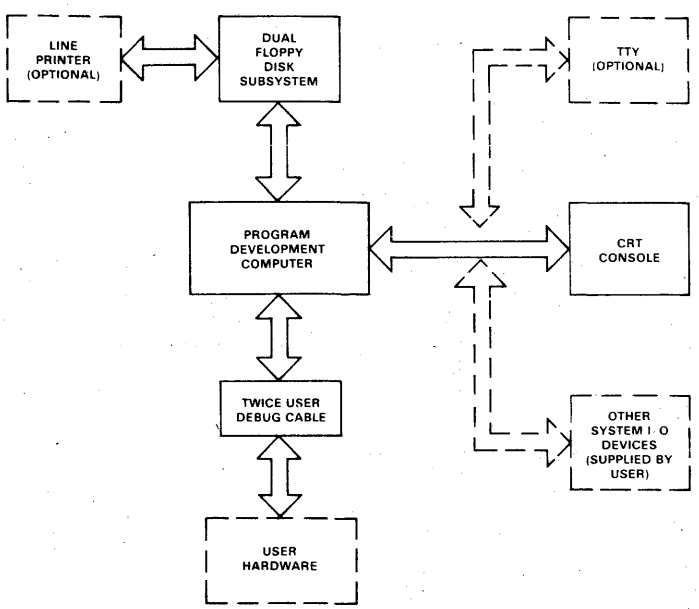

Figure 1

TWIN HARDWARE

The TWIN system is available in two configurations: the BASIC TWIN and the SUPER TWIN.

Basic TWIN Configuration

Program Development Computer consisting of:
- Master CPU—16K Master Memory
- Slave CPU—16K Slave Memory
- Debug Logic Card

TWICE Cable
Dual-Drive Floppy Disk Subsystem

Super TWIN Configuration

Basic TWIN configuration plus:
- 1702A PROM Program card
- 82S115 PROM Program card
- General-Purpose I/O Card

CRT Console
Line Printer

Program Development Computer

The Program Development Computer (PDC) is the principal subsystem of the TWIN. The PDC employs dual-processor architecture operating on a common bus structure.

The Master/Slave architectural concept provides the following features:

1. Protected operating system memory and I/O.
2. Complete user access to slave memory address space and I/O address space.
3. Operating system and Debug software are independent of user programs.
4. Use of future Slave processors by adding boards and supplying additional software only.
5. Multiple Slave CPUs of different types can be accommodated.
6. Debug and TWICE hardware.

The PDC can be divided into four distinct areas as shown in Figure 2.

1. The master CPU provides access to all support peripherals (Floppy Disk, Line Printer and CRT console). By way of the common bus, the slave side of the system can make requests of these system peripherals. In addition, via the General Purpose I/O Board, the user has the option of adding system peripherals on the master side.
2. The master CPU controls PROM programming by transferring data from the slave memory to the PROM sockets. Both erasable (1702A) and nonerasable (82S113) PROMs can be programmed through sockets controlled by the operating system.

©IC MASTER 1979

THE TWIN SYSTEM

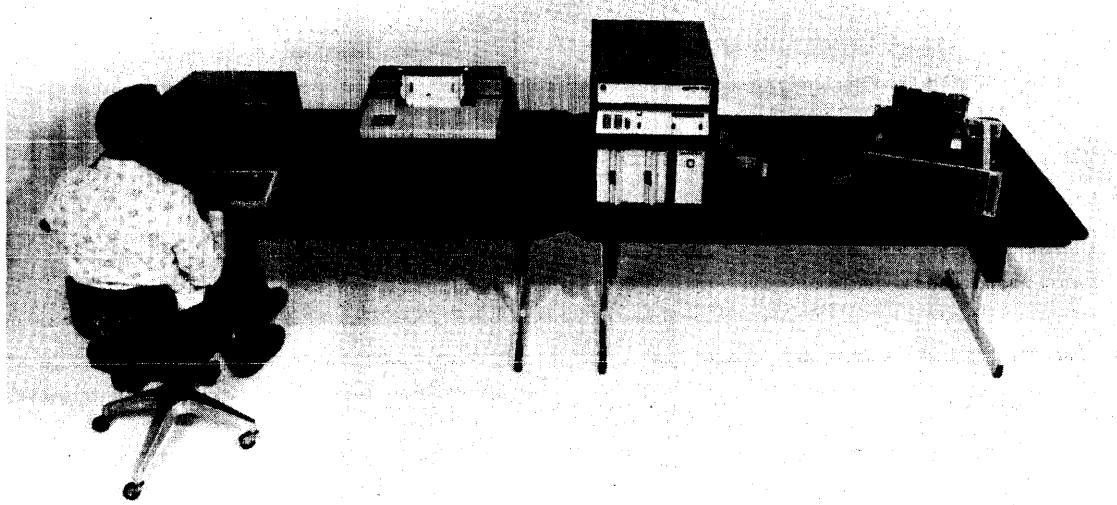

Figure 4

Text Editor

The Text Editor is a comprehensive software package that allows the user to enter and modify text files. The Text Editor is line oriented and accepts inputs from the terminal or a diskette file, performs modifications in a work space, and outputs the revised text to diskette file.

Assembler

The Prototype Development System Resident Assembler translates symbolic assembly language instructions into appropriate machine language code.

The Assembler is written in the Signetics Higher-Level Language (PLμS) and generates absolute object code. This code is in hexadecimal format and may be loaded into the system for direct execution or may be converted by an SDOS command to SMS format for PROM or ROM programming.

Debug

The debug system is a software program which provides the user with real-time program debug capabilities within both a software and hardware environment. It uses special hardware features built into the program development system to control the execution of the user's program. User programs operating under the debug system have dynamic program trace, breakpoint capabilities, and memory modification capabilities. Status reporting on the memory, the program, and the processor is also provided.

PHYSICAL AND ENVIRONMENTAL SPECIFICATIONS

	VOLTAGE	VOLT AMPERES	LINE FREQUENCY (HERTZ)	WEIGHT (POUNDS)	DIMENSIONS (INCHES)
Development Computer	115 ± 10%	230	47 — 63	65	8 x 17 x 22
Dual-Drive Floppy Disk	115 ± 10%	400	59.5 — 60.5	85	10 x 17 x 22
CRT Console	115 ± 10%	130	47 — 63	52	14 x 17 x 22
Printer	115 ± 10%	375	59.5 — 60.5	66	12 x 23 x 19

NOTE

Export version will operate from other line voltages and frequencies.

Table 1 SUBSYSTEM CHARACTERISTICS

Total System Characteristics

Operating Temperature Range: 15° — 37°C

Operating Humidity Range: 50% — 80% NC

Basic system shipping weight: 180 pounds

Card Cage—Mother Board Assembly

7 x 11 cards/20 slots in PDC

Common Bus Structure

External +5V ground bus (spare with rear panel terminals)

Front Panel Switches and Indicators

Key-operated primary power On/Off switch

PROM power switch

Reset switch that initializes system and sets both CPUs to location zero, enables master, and pauses slave.

Diagnostic interrupt switch

Power indicator

Run indicator

Master indicator

Slave indicator

PROM power indicator

DESCRIPTION

The Signetics Adaptable Board Computer, ABC 1500, is a modular microcomputer containing a CPU, memory, I/O ports and support circuitry. It is designed to cover a broad range of applications from software development to system hardware prototyping. Cost performance trade offs have been carefully considered to achieve maximum flexibility and allow the card to be tailored to a variety of individual requirements.

The basic configuration consists of the 2650 8-bit microprocessor, 512 bytes of read/write memory (four 2112 static RAM's), 1k bytes of 2608 ROM with PIPBUG*, two 8T31 I/O ports and buffering on data, address and control lines. A single +5 volt supply will be required to power the card and communicate with a serial 20mA current loop terminal.

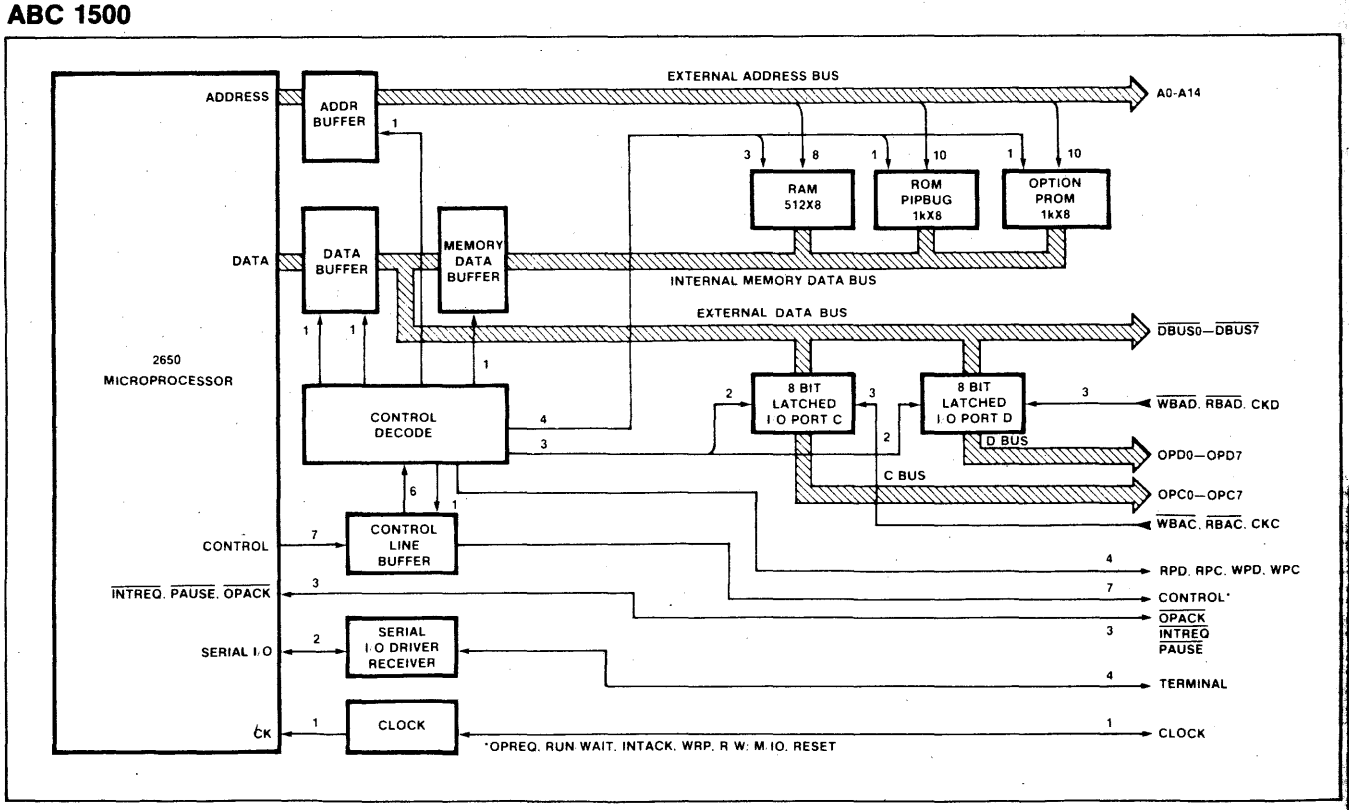
Modifications to the basic system can be easily made to allow for various memory configurations and operating modes. Unused plated through holes are provided for the PROM memory chips (82S115's). Other options are jumper selectable.

The ABC 1500 is sold either as a completely assembled and tested card (2650PC1500) or in kit form (2650KT9500).

*PIPBUG is a loader, editor, and debug program. See Table 1.

FEATURES

- Expandable printed circuit card: Unused area on card filled with plated through holes on .300 in. centers for wirewrap sockets
- 1k bytes of PIPBUG* ROM (in socket)
- 512 bytes of RAM
- Two latched I/O ports —four non-extended I/O read/write user strobes
- Tri-state buffers on data, address and control lines
- Serial input/output port
- Single +5 volt supply requirement (1.7A max) for card and 20mA current loop interface (±12 volt supply for RS232 interface)
- Interrupt and single step capability
- Simple clock configured from dual monostable multivibrator
- 24k memory expansion capability
- Directly compatible with 4k RAM card (2650PC2000) and power supply demonstration base (2650DS2000)
- Card dimensions: 8 in. by 6.875 in. with a 100 pin connector along the 8 in. dimension



OPTIONS

- 1k bytes of PROM in place of ROM
- 512 bytes of PROM or ROM in place of RAM
- Asynchronous operation capability
- External clock input
- Interrupt vector from Port C

INTERFACE

- Terminal interface jumper selectable
  A. W4 to W5 and W6 to W7 jumpers select the 20mA current loop mode
  B. W3 to W4 and W7 to W8 jumpers select the RS232 mode
- Normally high input lines (10k pull up resistor on each): $\overline{\text{INTREQ}}$, $\overline{\text{PAUSE}}$, $\overline{\text{RESET}}$, $\overline{\text{WBAC}}$, $\overline{\text{WBAD}}$, CKC, CKD
- Plated through holes are available at each connector pin to allow for insertion of wirewrap pins.
- Edge connector supplied with card
- To allow for external clock input, remove jumper W9-W10
- Asynchronous operation by removing jumper W1 to W2 and driving $\overline{\text{OPACK}}$
- During vectored interrupts, it is possible to allow port C to place the interrupt address on the data bus by removing jumper W21-W22 and jumpering W22-W23

ABC 1500

©IC MASTER 1979

DESCRIPTION

Signetics offers one of the broadest choices of microprocessors . . . that translates to a broad understanding of microprocessors. This knowledge has gone into the development of the Instructor 50[tm]. Learning about the operational aspects of a microprocessor and how to program one is no easy task. Listening to long-winded lectures and sharing hands-on experience with ten other people during the last twenty minutes of a session are no way to learn about microprocessors, particularly when it comes to programming one.

That's precisely why we've developed the Instructor 50[tm] — to teach you about microprocessors and microprocessor programming the easy way, and "right in your own back yard." With the Instructor 50[tm] package, you have a complete microcomputer system right at your fingertips.

Instructor 50[tm] is a practical, low-cost microprocessor training tool. Its primary function is to teach you microprocessor operation, programming and applications. Even if you've never used a computer of any kind, you'll find that Instructor 50[tm] can help you learn and apply computer concepts very quickly.

FEATURES

- **Ready-to-run desktop unit with integral power supply.**
- **16-key hexadecimal keyboard for entering data values.**
- **12-key command function keyboard for issuing commands and selecting operating modes.**
- **Eight-digit LED display lets you instantly see results of your processing.**
- **Audio tape cassette interface allows you to create program library.**
- **S-100 interface bus permits system expansion.**
- **USE monitor program supervises operation of the system.**
- **Debugging aids, including breakpoint and single-step modes.**
- **Parallel and serial I/O.**
- **512 bytes of on-board user RAM.**
- **Crystal-controlled system clock.**
- **Comprehensive User's Guide and Introductory Manual.**
- **Port data input switches.**
- **Port data indicators.**
- **Direct/indirect interrupt switch.**
- **Port address select switch.**
- **FLAG and RUN indicators.**
- **Use of the powerful 2650 8-bit, N-channel microprocessor, with fixed command set of 75 instructions and eight different addressing modes.**

Each Instructor 50[tm] comes with a Warranty card, which offers parts replacement and related labor at no charge for 90 days after purchase. For repairs, simply ship the compact, lightweight unit to Signetics headquarters in Sunnyvale, California.

©IC MASTER 1979

Who Needs Instructor 50™? Research engineers, scientists, design engineers, engineering managers, instrumentation specialists, computer professionals, educators, students and hobbyists, to name a few. In fact, anyone desiring in-depth knowledge of how a microprocessor functions will benefit from Instructor 50™.

Instructor 50™ effectively supports college and university curricula by illustrating basic computing concepts. Educators who previously taught these fundamentals only through textbooks, lectures, and paper exercises now have a means by which their students can apply classroom instruction. Using the Instructor 50™, the student can write, enter and test his own programs, and observe the sequence of events associated with instruction execution.

Whether used in the classroom, office or home — the Instructor 50™ reinforces basic concepts, and provides the important "hands-on" experience to illustrate microcomputer functions.

No Experience Required. Plug in the Instructor 50™ — and the first message you'll read on the prompting display is "Hello." This friendly, interactive display combines with an exceptional ease of program entry to make the Instructor 50™ an ideal system for the novice.

There's absolutely no previous microprocessor experience required to use the Instructor 50™. This complete learning package comes with a User's Guide — plus a special introductory manual written just for the beginner. Also included is an audio cassette recording with helpful hints to assist you. On this cassette, you'll find interesting programs (e.g., clock, stopwatch and crap game) that you can run and enjoy right from the start.

While the Instructor 50™ "shakes hands" with the novice, its broad hardware/software capabilities can also challenge the pro. Accordingly, the Instructor 50™ is ready to handle more sophisticated applications when you are.

Fully Operational Microcomputer In One Package. Instructor 50™ minimizes the time and expense involved in learning the operation and programming of a microprocessor. A complete, ready-to-run unit with its own integral power supply, it features separate command and hexadecimal keyboards and an LED prompting display. The system includes everything you need to write, run and debug machine-language programs — housed in one compact package.

Build a Library of Program Tapes. You can save your programs on any ordinary cassette recorder tape. Simply depress the WCAS (write to cassette) key , and the Instructor 50™ will record your program onto a tape cassette. Later, you can rewind the tape, depress the RCAS (read from cassette) key, and reload computer memory. By saving your programs on tape, you can easily create your own library of programs.

Monitor Firmware Makes It Easy. The USE (User System Executive) Monitor firmware makes the Instructor 50™ the best system of its kind. Most systems require start-up procedures before a program can be loaded or executed. The Instructor 50™ does not. Its USE Monitor program runs automatically as soon as the system is turned on. And an LED display provides helpful prompting and error messages.

While in the monitor mode, you may:

- **enter and alter a program.**
- **read in a previously saved program from audio cassette tape.**
- **display and alter the contents of the microcomputer's general purpose working registers and/or Program Status Word.**
- **examine and alter the contents of the Program Counter and memory locations.**
- **specify and examine a program breakpoint.**
- **step through a program one instruction at a time.**
- **save a program on cassette tape.**
- **begin execution of a program you have written.**

Space for Expansion.* Equipped with an S-100 type expansion interface, the Instructor 50™ can be converted from a learning device to a small system computer — limited only by the number and type of peripheral boards used. Moreover, the powerful program/data entry and debug facilities of the basic Instructor 50™ can be extended to any device connected to the S-100 bus interface.

Heart of the System. The Instructor 50™ uses the Signetics 2650 microprocessor as the central processing element. Recognized as the microprocessor "most like a minicomputer," the 2650 reads instructions from program storage and, by executing these instructions, performs all the arithmetic and logical operations required. The 2650 also provides the system program with the physical means to access and control the system's input and output functions.

©IC MASTER 1979

FUNCTIONAL DESCRIPTION

- **Eight-Digit Display Panel.** This versatile display helps you learn by visually reinforcing the data the moment you enter it into the Instructor 50™. With it, you may examine and alter internal data, set up program parameters, observe the effects of your program one step at a time, and even write a program to display your own messages. Presenting some alphabetic, as well as numeric characters, it prompts you to enter necessary parameters and even tells you when you've made an error!

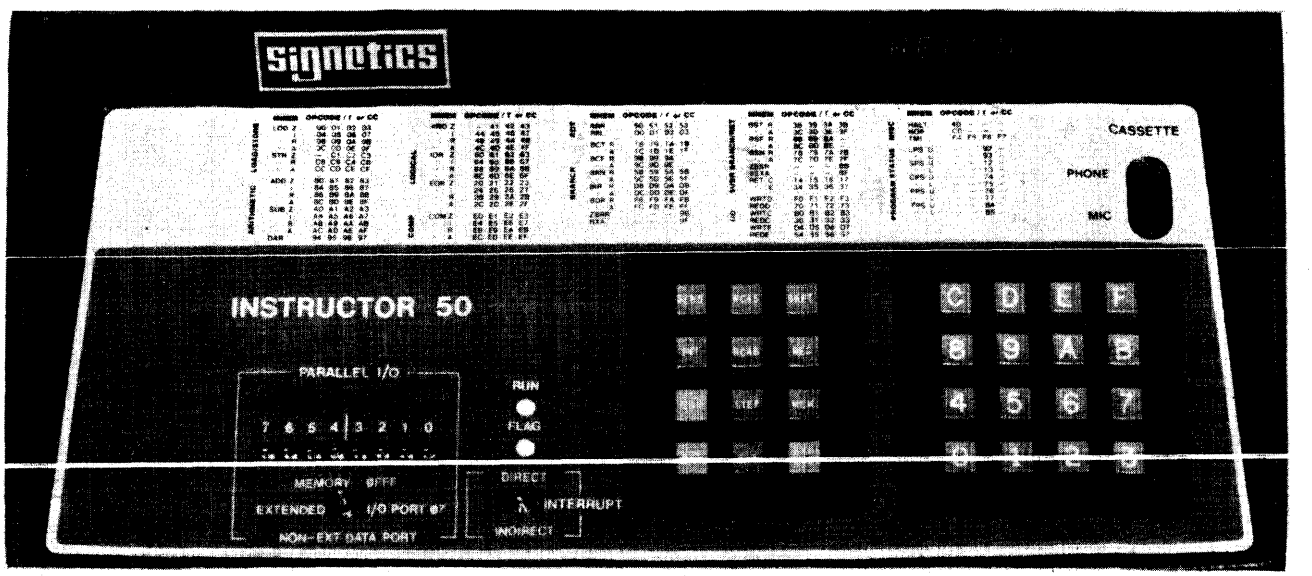
- **Cassette Connectors.** Virtually any audio cassette recorder can be hooked up here — and we supply the cords with the Instructor 50™. Use this connection to read a program into the microprocessor or take the program you've written through the keyboard and save it on an audio cassette tape.

- **Hexadecimal Keyboard.** Most professional programmers use the hexadecimal (base 16) numbering system. If you're not already familiar with this system, you'll learn about it in the Introductory Manual. And after a few turns at this keyboard, you'll understand why the hexadecimal system is preferred and how you can successfully use it for "machine language" programming.

- **Functional Control Keyboard.** Each of these 12 buttons commands the Instructor 50™ to perform a pre-defined operation as described in the Users' Guide. And three of the most used functions are color coded to make the keyboard even faster and easier to use.

- **Direct/Indirect Interrupt Switch.** This switch lets you learn and understand an important programming concept, direct and indirect "interrupt vectoring." The Instructor 50™'s 2650 microprocessor is one of the few to offer this sophisticated feature.

- **Port Address Select Switch.** This 3-position switch is used in conjunction with the Port Data Indicators and Port Data Input Switches. By providing three different ways to connect this "input/output" port to your microprocessor, it illustrates important tradeoffs that system designers must make.



- **Port Data Input Switches.** Connected to an "input port," these eight rugged, numbered switches let you select up to 256 input combinations! You're limited only by your desire to learn with these simple switches at your command. Similar to the control switches found on large computers, they allow you to control the program flow of the microprocessor. Tell it what program to run. Or even use one or more of the combinations to play blackjack or a similar game.

- **Port Data Indicators.** These eight LEDs connected to an "output port" are your direct line to data within the 2650 microprocessor — the heart of the Instructor 50™. As they blink they're showing you the actual "ones" and "zeroes" being outputted from your unit. As your experience with the Instructor 50™ increases, you will gain a clear understanding of the internal operations of your learning tool.

- **Flag Indicator.** This LED signals the "Flag" condition, a special feature of the Instructor 50's 2650 microprocessor. This visual monitor lets you know when you've reached a limiting condition such as calculator overflow, or when you've reached a certain point in your program. It also can be used to illustrate "serial communications" concepts.

- **Run Indicator.** Another special monitor. This LED keeps a constant watch on the "run" signal of the 2650 microprocessor. And it's a straightforward way to verify that the 2650 is running a program — not in a paused or halted mode.

- **Instruction Reference Chart.** Before you know it, operating the Instructor 50™ will become second nature to you. But to make it even easier, we've printed a chart with basic instructions right on top of the unit. So in most cases, you won't need to refer to the comprehensive User's Guide or Introductory Manual that also come with your unit.

ALTERNATE SOURCE DIRECTORY

The Alternate Source Directory is an industry-wide cross reference of those devices which manufacturers claim are pin-for-pin and functional equivalents to IC's made by other firms. It is a compilation of many individual references and shows literally thousands of alternates that aren't implied by their model numbers, especially in the linear and memory areas. Unlike the usual alternate source guides, this directory leads you to many alternate sources for any particular device, not just one. It is the most comprehensive alternate source directory ever published and contains over 44,000 cross references.

how to use the alternate source directory

The second column of this Alternate Source Directory shows devices which are replacements for those in the first column. Devices listed in **BOLD FACE** type have technical data in the Master Selection Guide. This information begins on the page listed to the right of the **BOLD FACE** part numbers. Products preceded by a ♦ have been discontinued by the manufacturer. This section does include devices not listed in the Master Selection Guide; e.g., discontinued items, DTL and 54L devices.

This list is compiled from manufacturers' recommendations. Since there is a tendency for every company to show only itself as an alternate to the prominent manufacturers, and for the larger ones to ignore the smaller ones, not every device is referenced both ways to every other one. Therefore, if you are looking for alternates to a lesser known company's device, take the replacements you find, especially if they are made by prominent companies and look them up to see if you can find any other sources.

In order to maintain this list within some reasonable bounds, the A and B suffixes indicating improved versions generally have been dropped. If this weren't done, for example, every higher speed selection conjured up by a memory manufacturer would result in a device that could replace many equal or slower competitors and this directory would become highly involved in slight performance variations. Moreover, improved performance is only important if your circuits take advantage of it.

One of the difficulties with any cross reference is that devices meant to be alternates do not necessarily perform the same in all circuits. Thus, it will be necessary for you to check specifications, or even to check circuit performance before deciding which alternates are right for you. A major benefit of this list is that it gives you more alternatives to study. But if you don't find what you need here, it may be possible to find additional alternates by locating the device in the Master Selection Guide. Particularly for digital circuits, the other products grouped with it will normally offer similar or identical performance.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

Fairchild (cont'd)

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

◆ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

› Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

◆ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

Siliconix

DF320	Nitron	NC320
DF321	Nitron	NC321
DF322	Nitron	NC322

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

Texas Instruments (cont'd)

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

MANUFACTURERS AND DISTRIBUTORS / REPRESENTATIVES DIRECTORY

The Manufacturers and Distributors/Representatives Directory is a comprehensive telephone directory of the entire IC industry. It places at your fingertips the names and phone numbers you need to know. It includes manufacturers, field sales offices, representatives and distributors. The manufacturers' listings tell you where and whom to call to obtain technical and ordering information. It enables you to ask for the right person or phone extension. It gives you the terminology understood by the individual company's switchboard operators, e.g, in some companies you should ask for sales, in others, customer service. This directory will reduce frustration and save you time.

Advanced Micro Devices

Advanced Micro Devices, Inc.
901 Thompson Place
Sunnyvale, California 94086
(408) 732-2400
TWX: (910) 339-9380
Telex: 34-6306
Federal I.D. 34355

Specific product information:
Bipolar Microprocessors ..... John Springer
Bipolar Memory ..... Ralph Cognac
Logic (MSI) ..... Mike Walton
Hi-Rel Logic and Interface ..... Len Seib
MOS Microprocessors and Support Circuits ..... Randy Crume
MOS Serial Memory, Mask-programmable ROM's and E-PROM's ..... Bill DeMatteis
MOS-RAM's ..... Lowell Turriff
Computer Interface ..... Al Tremain
Linear ..... Steve Thompson

Application engineering:
Bipolar Digital Products ..... Roy Levy
MOS Products ..... Joe Kroeger
Linear Products ..... Russ Apfel

Literature ..... Literature Dept.
Price and delivery ..... Contact AMD Sales Office, Rep. or Dist.
Follow-up on orders ..... Customer Service Dept.
All other information....Corporate Communications Dept.

Specific product information:
Local field sales office or franchised distributor, or contact the specific product marketing department at 464 Ellis Street, Mountain View, CA. Request through main switchboard: (415) 962-5011:
LSI Products....
Microprocessors (MOS, Bipolar, ECL)
Memories (Bipolar, MOS, CCD)
LSI Logic (ECL, MOS, CCD)
Analog (CCD)
IC Components
Digital SSI & MSI (TTL & CMOS)
Linear
Interface
Hybrid
Discrete
Diode
Transistor — Power & Small Signal
OPTO
